

BANXUM

by Garanta Finanzgruppe AG

Admin Console Operations Manual

A visual, step-by-step guide for new operations staff

INTERNAL & CONFIDENTIAL

This manual teaches the BANXUM peer-to-peer lending model from zero and walks through every screen of the internal admin console, with annotated screenshots and end-to-end workflows.

Screenshots captured in preview mode; all names and figures shown are demo data.

Contents

- 1. Part 1 — The BANXUM model in plain language
- 2. Part 2 — Getting into the console
- 3. Section 3 — Daily Dashboard
- 4. Section 4 — Tasks
- 5. Section 5 — Users
- 6. Section 6 — Compliance
- 7. Section 7 — Finance Operations
- 8. Section 8 — Loans & Marketplace
- 9. Section 9 — Reports & Audit
- 10. Section 10 — Superadmin Settings
- 11. Section 11 — End-to-end workflows
- 12. Section 12 — Glossary & quick reference

How to use this manual

- Start with Part 1 if you are new to BANXUM or P2P lending.
- Use Sections 3-10 as screen-by-screen training references.
- Use Section 11 when you need a click-by-click workflow.
- Use the glossary when a status, queue, or finance term is unfamiliar.

BANXUM P2P Primer: what you need to know before you touch a screen

1. What BANXUM is

BANXUM is a peer-to-peer (P2P) lending marketplace. "Peer-to-peer" means individual people lend money directly to businesses, instead of a bank sitting in the middle and lending its own money.

Here is the basic idea. Individual investors (we also call them "lenders") put money into BANXUM. That money is then used to fund loans to vetted business borrowers. The borrowers pay the money back over time, with interest. The interest is shared back to the investors who funded that loan. Investors can later take their money out again.

BANXUM is operated by Garanta Finanzgruppe AG, a Swiss financial group. "Garanta" is the operator, and you, as an operations admin, work for Garanta. BANXUM does not lend its own money and is not a bank. It runs the marketplace, checks who everyone is, moves money correctly, and keeps records.

This manual is about the internal ops console served at /admin, which only Garanta staff use. It is NOT the app that investors log into. Throughout this manual, "the console" or "the admin console" always means the staff tool, never the investor app.

2. The four people in the story

Almost everything in BANXUM involves these four parties. Learn them first; the rest of the manual refers to them constantly.

- **Investor (lender):** an individual who deposits money and funds loans to earn interest. In the system an investor account has an `account_type` of either `"natural_person_lender"` (a real human investing for themselves) or `"legal_entity_lender_representative"` (a person acting on behalf of a company that invests). Every lender account is given a short unique `investor_reference` code when it is created. Investors log into the investor app themselves; they do not use the admin console.
- **Borrower:** a company that receives a loan and pays it back with interest. A borrower is NEVER a login account. It is a record (a `"BorrowerEntity"`) that you, the admin, create and maintain by hand. The borrower has no portal, no password, and never logs in anywhere. Borrowers are vetted through KYB (explained in section 7) before they can receive money.
- **Garanta operator (you):** a Garanta staff member working in the admin console. There are two staff account types: `"admin"` (normal operations staff) and `"superadmin"` (staff who can also change platform-wide settings and create other admins). Note that the account type alone is not enough: admin powers also depend on the account's `is_staff` flag being set, and superadmin powers additionally require the `is_superuser` flag, so a `"superadmin"` account type that lacks `is_superuser` would not pass superadmin checks. You enter borrowers and loans, review compliance, confirm bank movements, and run the day-to-day operation.
- **Didit:** an external identity-verification company. "External" means it is a third-party provider, not part of Garanta. When a person needs their identity checked, BANXUM sends them to Didit. Didit runs the identity and anti-money-laundering checks and reports the result back. The default identity provider on every verification case is `"didit"`.

3. How money moves

Money flows in one big cycle. Follow it once and most screens will make sense.

Step 1, the investor sends a bank transfer. The investor wires money from their own bank to a Garanta collection bank account. "Collection account" just means the Garanta-controlled bank account that receives investor money.

Step 2, the transfer is matched and ledgered. When the money arrives, an admin confirms the bank operation and records it in the ledger (the system's official books), including the payer/source IBAN shown on the bank statement. The source IBAN must pass full checksum validation and then automatically becomes a verified payout account for that investor and currency. Crucially, the investor must also put a specific payment reference on their transfer so we can tell whose money it is. That reference has the exact format `BX-{currency}-{investor_reference}`, for example `BX-CHF-AB12CD`. The CHF deposit screen also shows a verified Swiss QR-bill code for `Garanta_CHF`, but that code identifies the collection account only; it does not replace the investor-specific BANXUM reference.

Step 3, the money becomes an investable balance. Once matched, the deposit creates a "balance lot" (think of it as a dated parcel of that investor's money) and the amount becomes investable. Balance buckets are explained in section 5.

Step 4, the investor invests in a loan (the primary market). The investor places an investment order against a published loan. Their investable balance is reserved for that loan. When the loan finishes funding, the reserved money is committed to it.

Step 5, the borrower is disbursed. Once a loan is fully funded and the borrower's KYB is approved, an admin pays out (disburses) the loan principal to the borrower's bank account.

Step 6, the borrower repays. Over the loan term the borrower sends money back to a Garanta collection account. Every payment follows one fixed order: Garanta legal costs/recovery fee, penalty, contractual interest, then principal. An admin records the evidence and amounts due; the server applies that order and distributes lender-facing amounts in proportion to current holdings.

Step 7, returns land back in the investor's balance. Each investor's share of principal and interest is credited back to their BANXUM balance as new balance lots.

Step 8, the investor withdraws to their bank. They can use a verified source account established by a deposit or request verification of another IBAN. An additional self-service request opens an admin finance task and remains unusable until reviewed. An admin then finalises the requested withdrawal after the bank transfer executes, or cancels it before execution.

- Deposit reference format: BX-{currency}-{investor_reference}. It must appear, unchanged, in the bank transfer reference field, even when the investor uses the CHF QR-bill code.
- Money only moves between real bank accounts at deposit (step 1-2), disbursement (step 5), repayment (step 6), and withdrawal (step 8). Everything in between is internal bookkeeping in the ledger.
- Every money movement is recorded as a balanced double-entry journal in the ledger, and every confirmed bank transfer is recorded as a "bank operation". These records are append-only: they are never edited or deleted, only added to or reversed with a new entry.

4. Money in BANXUM is not a bank account

This is the single most important idea for an operations admin. An investor's BANXUM balance is NOT a savings account.

The balance is non-interest-bearing operational money. "Non-interest-bearing" means simply holding money in BANXUM earns the investor nothing; interest only comes from funding loans. "Operational" means the balance exists so the investor can invest or withdraw, not to park cash. The funds are also segregated, meaning investor money is kept apart from Garanta's own money, not mixed with it.

Because BANXUM is not a deposit-taking bank, regulators do not allow investors to sit on idle cash indefinitely. So every balance lot is subject to ageing. Ageing means a parcel of money has clocks running against it from the day it was received, and what the investor is allowed to do with it changes as those clocks pass.

There are two ageing windows, measured from when the money was received:

Investment eligibility depends on the loan's remaining funding window, not a fixed day-30 cutoff. A 30-day remaining window needs at least 30 holding days left on every consumed source; a 10-day window needs 10. The final subscription date must precede the source's day-60 deadline. Funding windows contain at most 50 inclusive subscription dates. Eligible sources are consumed oldest-first.

The 60-day window (the withdrawal deadline). At 60 days the lot has reached the regulatory holding limit and must leave BANXUM. The investor cannot extend this deadline and neither can Garanta. The system sends the investor reminder emails as the deadline approaches (around days 25, 46, 53, 58, 59 and 60).

What happens when a lot reaches or passes the 60-day limit depends on whether the investor has given us a usable bank account to send the money to. "Usable" means a payout instruction (a registered IBAN) that an admin has verified. The handling fires on the first balance ageing scan at or after the deadline (the scan treats a lot as overdue once the business date is on or past the withdrawal deadline), so a lot already past 60 days is swept up too, not only one exactly on day 60. Two outcomes are possible, handled automatically by the balance ageing scan.

- Forced withdrawal: if the investor HAS a verified, usable payout IBAN when a lot reaches or passes the 60-day limit, the system automatically creates a withdrawal request for that overdue money. "Forced" means the investor did not ask for it; the system raised it for them to honour the deadline. An admin then finalises the bank payout like any other withdrawal.
- Penalty mode: if the investor has NO verified usable IBAN when a lot reaches or passes the 60-day limit, the system cannot send the money out, so the lot is moved into penalty mode. In plain words, a small daily charge starts eating into that specific balance (a per-day penalty in basis points, set as a deployment-level configuration value applied platform-wide; it is not a toggle you edit in the console). When any of the investor's money is in penalty mode, the investor app raises a blocking-severity "usable IBAN required" alert on their dashboard, prompting them to register a usable payout IBAN. Penalty-mode lots cannot be used for new investments, and the backend also blocks FX exchanges and secondary-market purchases while any penalty-mode balance exists. Withdrawal remains the intended exit path. If the daily charges ever consume the whole lot, it becomes penalty-exhausted (nothing left to charge).
- Frozen: a separate balance lot status used when a lot is administratively held (for example during a compliance review). Frozen money still belongs to the investor but cannot be invested or withdrawn until the hold is lifted. Frozen is set deliberately, not by the ageing clock; penalty mode is what the 60-day clock produces when there is no usable IBAN.

5. The balance buckets

When you look at an investor's money, it is grouped into buckets. A bucket is just a label describing what the investor can currently do with that money. The bucket is decided per balance lot, from the lot's status and its two ageing clocks. The same investor can have money in several buckets at once.

Only money that is genuinely still sitting in the balance (the "available" amount of a lot) counts toward these buckets; money already invested, withdrawn, converted in an FX exchange, or eaten by penalties does not.

- investable: available money before its holding deadline. This is a potential amount: each loan's remaining funding window must fit within each consumed source's holding time. Shorter windows can use older funds.

- **withdraw-only:** a compatibility bucket, normally zero under the current policy. There is no automatic day-30 investment ban. At day 60, uninvested funds instead enter the overdue return process.
- **overdue:** available money past the 60-day withdrawal deadline. It is over the regulatory holding limit and must leave BANXUM. This is what the ageing scan turns into a forced withdrawal (if a usable IBAN exists) or penalty mode (if not).
- **frozen:** money in a lot that has been administratively frozen. The investor can neither invest nor withdraw it until the freeze is removed.
- **penalty:** money in a lot in penalty mode, being charged a daily penalty because it passed 60 days with no usable IBAN. Any penalty-mode balance raises a blocking-severity "usable IBAN required" alert in the investor app prompting them to fix their payout details. The penalty-mode lot itself is not investable, and current backend gates also block FX exchanges and secondary-market purchases until the situation is resolved. Withdrawal remains allowed so the money can leave the platform.
- **available (total):** a roll-up of all of the above that still has money in it. It is the sum of every bucket; it is not a separate spendable pot of its own.

6. The life of a loan

A loan moves through a fixed set of statuses. Knowing the order tells you what is and is not allowed at each step.

draft: the loan exists only as an internal record an admin is preparing. Investors cannot see it. It can still be edited freely.

published: an admin has published the loan to the marketplace, so investors can now see it and invest. A loan can only be published from draft, and only when its required fields, repayment schedule, funding window and the borrower's KYB gate all pass. Once published it has a `published_at` timestamp.

funded: enough investor money has been committed and an admin closes funding. Only a funded loan can be disbursed to the borrower. (Funding can also be cancelled before close, returning reserved money to investors; a never-funded loan can end up cancelled.)

performing vs late vs defaulted: after disbursement the borrower repays on a schedule. As long as installments are paid on time the loan keeps performing (its status stays funded). If an installment is overdue by 5 days or more the system marks the loan late. If an installment is overdue by 16 days or more it is marked defaulted.

repaid: the borrower has paid everything back. The loan is complete and investors have received their principal and interest.

defaulted then recovery or written-off: a defaulted loan moves into recovery, where Garanta tries to collect what it can (for example by enforcing collateral). Money recovered is distributed to investors. If nothing more can be collected, the remaining amount is written off, meaning it is formally recognised as a loss to the investors who funded it.

Primary market vs secondary market, in one line each:

- **Primary market:** where loans are funded for the first time. An investor places an investment order on a published loan, their balance is reserved and allocated, and when funding closes the money is committed and the borrower is disbursed. This is the normal way money goes into a loan.
- **Secondary market:** where an investor who already holds a piece of a loan resells that holding to another investor before the loan finishes, to get their money out early. The seller lists the holding (sometimes at a discount or premium); a buyer pays for it; Garanta takes a fee from each side. Some listings publish automatically and some need admin approval.

7. Gates that protect everyone

BANXUM blocks risky or non-compliant actions by design. These blocks are called gates. The most important thing to understand: gates are enforced on the server (the backend), not just hidden in the screen. You cannot click your way past them in the admin console, and neither can an investor. If a gate is not satisfied, the action is refused server-side, full stop.

Identity gates. People are checked with KYC; companies are checked with KYB.

KYC (Know Your Customer) is identity and anti-money-laundering verification for a person, run through Didit. A KYC case has a status, and only one status, "approved", lets the person act. Every other status blocks them, including `not_started`, `pending`, `declined`, `manual_review`, `high_risk`, `sanctions_hit`, `pep_hit`, `adverse_media_hit`, `expired`, and `reverification_required`. A "sanctions hit" means the person matched a sanctions list; a "PEP hit" means they were flagged as a Politically Exposed Person (someone in or close to public office, who needs extra scrutiny). When Didit's automated result is unclear or flagged, the case goes to `manual_review`, where a Garanta compliance admin decides to approve, decline, or request re-verification. Company KYB is handled offline as described below.

Company KYB/AML is completed and retained by Garanta offline for borrowers, Loan Originators and legal-entity lenders. No platform company case or document pack is required. Explicit borrower compliance holds and Declined/Manual review decisions remain blocking. Missing, Pending or Expired optional records alone do not block transactions.

Phone verification. Sensitive money actions also require the investor's phone number to be verified. An account is phone-verified only once a verification challenge has been confirmed.

Account statuses. Every account carries a status: `pending_kyc` (the default for a brand-new account that has not finished verification), `active`, `restricted`, `locked`, or `closed`. Pending-KYC lender accounts may still log in so onboarding can resume, but they cannot use financial features yet. Restricted, locked, and closed accounts cannot log in; closing also makes the account inactive.

Putting it together for investors: the system only lets an investor reach financial features (balances, investing, withdrawing) when the account is an active lender AND the phone is verified. There is one more gate that depends on the account type. For a natural-person lender ("natural_person_lender"), that person must also have an approved KYC case. For a company representative ("legal_entity_lender_representative"), active-lender plus phone-verified is enough; there is no personal-KYC check on the representative, because Garanta completes company KYB offline; no stored company approval or documents are required. Miss a required gate and the financial screens are refused.

- For natural-person lender KYC, only Approved permits financial access. Company KYB is offline; explicit restrictions remain enforceable.
- Compliance hold overrides KYB: a borrower with approved KYB but an active compliance hold still cannot receive money.
- Gates live in the backend. The console will not offer an override button, because the rule is enforced where the money actually moves.

8. What the admin console is for

The console at /admin is organised into the main areas in the left-hand navigation. Here is each one in a single sentence so you know where to go.

- Daily dashboard: your morning overview, showing the work queues that need attention today (KYC reviews, bank exceptions, withdrawals, forced withdrawals, balance ageing, funding loans, servicing, loan risk, secondary approvals, FX settlement, failed emails, reconciliation breaks).
- Tasks: the admin task list, where operational to-dos are tracked and worked through.
- Compliance: review natural-person lender KYC, manual-review cases and Didit risk flags. Company KYB is handled offline.
- Finance ops: where money is handled, confirming deposits and bank operations, finalising withdrawals (including forced ones), running the balance ageing scan, handling FX (currency exchange) settlement, and doing reconciliation against the bank.
- Loans: where you create and edit borrowers and loans, publish loans to the marketplace, and close or cancel funding.
- Reports: where you generate operational and financial reports (for example FX delta and realised-settlement reports) for a chosen date range.
- Users: where you search the full user directory, inspect account state, open read-only investor views, and apply audited account access controls.
- Superadmin settings: superadmin-only configuration, such as document templates, platform settings and creating other admin accounts. QA mode is a separate staging/local section available to active regular admins as well.

9. Staging, production, and QA fast-forwarding

BANXUM has separate deployment contexts. Production is the real customer environment at nxnarena.com. Staging is the private testing and training environment at staging.nxnarena.com. Staging runs the real application stack, not the browser-only preview fixtures, but it is still a test environment: data can be changed, reset, or rolled back during QA.

Preview mode, staging, and production are three different things. Preview mode is local/demo UI data and is marked as not real account data. Staging is a live backend/database used for private testing. Production is the real operating environment and should be treated as legal and operational truth.

QA mode is a staging/local-only admin feature for testing time-based behavior. Active regular admins and superadmins can open the separate QA mode section when the deployment allows it. Production hides these controls and rejects their API requests even for superadmins. Never use QA mode with real customer funds, real customer onboarding or live-money provider actions.

When QA mode is entered, the system captures a database snapshot. While QA mode is active, BANXUM's business-time helper returns the simulated time instead of normal wall-clock time. Advancing time is day-based: for each Europe/Zurich business date crossed, the system runs the daily jobs that would normally happen in real time.

Fast-forwarding is intended to behave like real time for core platform jobs. It runs balance ageing and penalty charging, servicing status scans, primary funding-deadline resolution, reconciliation-break task sync, Loan Originator settlement-task sync, originator lifecycle scans and due email dispatch for the crossed dates. This lets admins test funding-window/day-60 balance behavior, forced withdrawals, penalty mode, late/default transitions, campaign expiry, automatic LO activation at funding close and scheduled notifications without waiting weeks.

Restore seed returns to the original regression seed, including its original simulated clock, accounts and balances. Create snapshot saves a later checkpoint without replacing that seed; Restore snapshot returns to this checkpoint. Without a manually saved snapshot, seed is the default and Restore snapshot is disabled. Records created after the selected restore point disappear. The restoring admin receives a fresh session if the restored credentials and permissions still match; all other sessions must sign in again.

- Use staging QA mode only for private testing, training, and regression checks. Do not use it to create legal production evidence or operate real money.
- Snapshot/revert covers database state, not already-sent email/SMS, downloaded files, object-storage artifacts or other external side effects. Restore checks the snapshot checksum and migration signature before an atomic flush/load; failure leaves the previous database intact. After schema migrations, the environment owner must upgrade the saved baseline in an isolated database or explicitly create a new seed; never bypass these checks.

- QA snapshot, restore and fast-forward take an exclusive environment lock. Concurrent application requests and scheduled jobs are refused temporarily. Fast-forward runs the relevant jobs for crossed dates. Do not run uncoordinated database scripts during QA operations.
- Coordinate with other testers, save evidence outside the database, then restore the seed between independent regression branches. Use Restore snapshot only when intentionally resuming that saved checkpoint.

10. Loan Originators: funding and activating an existing claim

A Loan Originator is a professional lender that already owns loans to final business borrowers. It can offer part of a performing loan through a finite BANXUM subscription round. Investor money is reserved during funding; it does not immediately become a holding or start earning interest.

Company KYB is completed and retained by Garanta offline; platform compliance files are optional. The final borrower's legal name is private unless an admin explicitly publishes it for that loan. Otherwise investors see its public display name. The originator has no BANXUM login or wallet; an internal payable tracks external transfers.

The underlying coupon is what the final borrower pays. The admin separately declares what percentage of attributable interest and penalty belongs to investors. Principal is subscribed at par: one currency unit of cash buys one unit of outstanding principal at activation. The displayed Yield is a nominal participating-coupon indicator, not a guaranteed effective return.

At full subscription, or after the funding deadline with any positive subscription, BANXUM closes the round and immediately creates active holdings and originator payable in one transaction. No separate activation action or borrower receipt is required. The boundary installment belongs entirely to the LO. Investor principal, interest and penalty rights follow the original published schedule after that boundary.

A processing failure preserves reservations, hides the opportunity and raises an urgent task plus operations email. Repair its cause promptly; automatic retries retain the published funding outcome. An admin cannot cancel a subscribed expired or failed round instead. A change discovered while funding is still open requires cancellation and a replacement opportunity before the deadline. Missing borrower payments after activation follow servicing, not an activation waiting stage. Incompatible legacy closed records raise a repair task without invented payment evidence.

Activation creates originator payable rather than borrower disbursement. Finance Operations settles accumulated activation and servicing payables in complete batches. A task appears when the oldest amount is three days old and settlement must occur no later than day five. There is no originator buyback or recourse guarantee.

- Use only the Loan Originator close, cancellation and repayment actions. Activation is automatic at close. Do not use direct-loan disbursement or direct servicing for LO claims.
- Do not publish from an unverified spreadsheet. Reconcile the full CSV to the legal contract, originator servicing export and bank evidence.
- Do not change the CSV simply to make validation pass. Put the opportunity on hold and investigate discrepancies.
- New refinancing-loan creation is disabled. Existing legacy refinancing loans remain readable and serviceable; Loan Originator claims are the new product for purchasing an existing loan claim.
- Only performing originator holdings are resellable in v1. Current holdings may be listed only at par or a discount; premiums are rejected. Private acquisition economics are never shown to a secondary buyer.

Getting into the console

The admin console lives at the `/admin` address of the BANXUM web app. It is completely separate from the investor app that lenders use. Only staff accounts of type *admin* or *superadmin*, with an active status, can sign in.

Signing in is two steps. First you enter your work email and password. Then BANXUM emails you a one-time numeric code, which you type on the next screen. This second step (an emailed code) is a security measure — even if someone learns your password they cannot get in without your mailbox. If you mistype the code too many times you must start again.

The layout. A dark navigation rail runs down the left with the areas of the console (described in the sections that follow). The main area on the right shows the selected area. A top bar shows where you are and who the operator is.

Preview vs. live data. When the console shows a small "Preview data" tag near the top right, you are looking at fixture (demo) data — safe for training and screenshots, not real customers. A live deployment has no such tag and every action affects real money and real people. *The screenshots in this manual were taken in preview mode, so the names and numbers are invented.*

Signing out. Use the "Sign out" button at the bottom of the left rail when you finish. Never leave an authenticated admin session unattended.

HOW TO READ THE FIGURES IN THIS MANUAL

- Each screenshot has small numbered green circles in the margins. A red arrow runs from each circle to the exact button, field, or column it describes, which is outlined in red.
- Below every screenshot, a numbered list explains each marked element in plain language — the number matches the circle.
- "Notes & rules" boxes call out the safety rules the system enforces and the mistakes to avoid.

Daily Dashboard

The Daily Dashboard is the first screen you see when you open the ops console, and it is the screen you start each shift on. Think of it as a control tower: it gathers the work that needs human attention from every part of the platform into one place, so you can see at a glance what is waiting and how urgent it is. (The ops console is the internal admin tool used by Garanta staff; it is separate from the app that investors and borrowers use.)

The screen has three parts. At the top is a row of four KPI tiles (KPI means 'key performance indicator' - a headline number you watch). Below that is the queues area: a left rail listing 13 work QUEUES, each with a live count, and a table showing the items inside whichever queue you have selected. At the bottom is a multi-currency balance summary table that shows the platform's money position broken down by currency (for example CHF and EUR).

A QUEUE is simply a named list of things that need looking at - for example loans waiting for funding, or investor withdrawals waiting to be paid out. Each item in a queue points at a real record elsewhere in the platform (a loan, a withdrawal, a bank transfer, and so on).

Most dashboard queues are read-and-route triage: you inspect context, then use the owning module. Withdrawal and forced-withdrawal rows are the deliberate exception. Their drawer embeds the bank-execution form so an admin can finalize an executed payout or cancel it before bank execution without navigating away.

WHAT YOU DO ON THIS SCREEN

- Read the four KPI tiles to gauge the overall load: how many items are open, how many are high priority, how many are past their deadline, and how many touch money.
- Scan the 13 queue tabs in the left rail and note the count badge on each - a non-zero count means there is work waiting in that area.
- Select a queue to load its table, then read each row's status, priority, due date and amount to decide what to handle first.
- Spot overdue items: rows that are past their due date (and not already finished) are highlighted so you can escalate them.
- Open an item's detail drawer to read its context and metadata. For withdrawal records, execute or cancel the request there; for other queues, continue in the owning module.
- Read the bottom currency table to understand the platform's money position per currency - what is investable, what is locked, what is overdue, and what is pending in bank or FX operations.
- On the Reconciliation breaks queue only, use the Create tasks button to turn open reconciliation exceptions into trackable admin tasks; use Refresh to reload the latest numbers.

Figure 3.1 The four KPI tiles across the top of the dashboard.

A row of four headline counters that summarise the entire dashboard at a glance. They are calculated from all 13 queues combined, not just the one you have selected.

- 1

Open queue items The total number of items waiting across all 13 queues right now. The small text underneath shows the timestamp the data was generated ('As of ...'). This is your overall workload number. Why it matters: if it is unusually high, the platform has a backlog; if it is zero, there is nothing waiting. Note that each queue is capped (the backend returns at most a limited number of rows per queue), so this is the count of items shown, which on a very busy day can be lower than the true total - lean on the per-queue counts and the bottom summary numbers for the real picture.
- 2

High priority How many of the open items are marked high, urgent or critical priority, with the number of strictly 'urgent'/'critical' ones called out underneath as '... urgent'. Why it matters: this tells you how much of today's work cannot wait. Watch out: priority is set on the underlying record, not here - this tile only counts what the queues report.
- 3

Overdue SLA How many open items are past their due date and not yet finished (an item counts as done only when its status is completed, finalized or settled). SLA means 'service level agreement' - the deadline by which something should be handled. The text underneath ('Window N days') shows the look-ahead window used for due dates. Why it matters: overdue items are the ones most likely to cause regulatory or customer problems; clear these first.
- 4

Finance actions A combined count of the money-movement queues: bank exceptions, withdrawals, forced withdrawals, FX settlement and reconciliation breaks. Why it matters: these queues involve actual cash and ledger accuracy, so this single number tells you how much finance-sensitive work is open. The subtitle lists exactly which queues are included.

NOTES & RULES

- All four tiles are derived numbers - they refresh when you press Refresh or when the dashboard reloads. They are not editable.

- These counters describe every queue combined; to see where the work actually sits, look at the per-queue counts in the next figure.

Figure 3.2 The queues area: the 13-queue rail on the left and the selected-queue table on the right.

The main working area. The left rail is a vertical list of 13 work queues, each with a live count. Clicking one loads its items into the table on the right. Each row opens a detail drawer; withdrawal and forced-withdrawal drawers also contain the executable finalize/cancel form.

- 1 Selected-queue title** Shows the name of the queue you are currently viewing (here 'Admin tasks'). It changes to match whichever queue tab you click in the left rail, and a one-line description and an 'N open' chip sit alongside it.
- 2 Column: Item** The short title of the work item plus, underneath, its 'kind' (an internal type tag such as admin_task or withdrawal_request). This is the column you read first to understand what each row is. The title is a clickable button that opens the detail drawer.
- 3 Column: Status** The current state of the underlying record, shown as a coloured chip. Green means a settled/healthy state (e.g. approved, active, reconciled, finalized, settled, completed); red means a problem (e.g. break, defaulted, dead_letter, penalty_mode); amber means it needs review (e.g. late, manual_review, pending_review); blue means in-progress/requested (e.g. requested, due, published, open). The colour is a quick triage cue.
- 4 Column: Priority** How urgent the item is, as a coloured chip. Urgent or critical shows red, high shows amber, low shows grey, and anything else shows blue. Use this together with the due date to decide ordering.
- 5 Column: Due** The deadline for the item - either a precise date-and-time or a date, depending on the record. If a row has no deadline this shows a dash. Rows whose due date has passed (and are not finished) are highlighted as overdue.
- 6 Column: Amount** The money value attached to the item, formatted in the item's currency. Many items have no monetary amount (for example a KYC review or a failed email), in which case this shows a dash. For funding loans this is the remaining principal still to be funded, not the full loan size.
- 7 Column: Object** Points at the exact platform record behind the row: an object type (e.g. Loan, InvestorWithdrawalRequest, KycVerificationCase) over a monospaced object ID. This is the reference you use to find and act on the record in the matching module screen.
- 8 Queue tab: Admin tasks (General)** Internal to-do items raised by staff or by the system (SLA follow-ups, operational notes). Populated from open admin tasks - any task not in a terminal state (resolved/cancelled) - sorted by due date. The number on the right is the live count of open tasks shown. This is usually where you start.
- 9 Queue tab: KYC reviews (Compliance)** Identity/AML checks that the automated provider (Didit) could not clear and that now need a Garanta decision. KYC means 'know your customer'; AML means 'anti-money-laundering'. Populated from verification cases in states like manual_review, high_risk, sanctions_hit, pep_hit, adverse_media_hit, declined or reverification_required. Act on these in the Compliance module.
- 10 Queue tab: Bank exceptions (Finance)** Incoming or outgoing bank/PSP transfers that the system could not match or that are still pending, so the money cannot yet be allocated on the ledger. PSP means 'payment service provider'. Populated from bank operations in status pending_review or unmatched. These block deposits/payouts from completing, so they are time-sensitive.
- 11 Queue tab: Withdrawals (Finance)** Investor withdrawal requests that have been accepted and are waiting for the actual bank payout to be executed and finalised. Populated from withdrawal requests in status 'requested', sorted oldest-first. Handle these in Finance ops (Withdrawal execution).
- 12 Queue tab: Forced withdrawals (Finance)** A subset of withdrawals that the system created automatically because money sat unused too long. By rule, funds that reach the 60-day return-of-funds point must be sent back to the investor; those generate a 'forced' withdrawal. Same underlying records as the Withdrawals queue but filtered to forced ones.

- 13

Queue tab: Balance ageing (Finance) Investor balance 'lots' (tracked chunks of deposited money) that are near or past the regulatory time windows. The rules: each reserved source must cover the loan's remaining funding period, and uninvested money must be returned by day 60. This queue surfaces lots already past the 60-day withdrawal deadline and lots stuck in penalty mode (waiting for a usable payout IBAN).
- 14

Queue tab: Funding loans (Marketplace) Direct loans still raising funds plus non-public funding-close failures that need intervention. Published campaigns are sorted by deadline; a `funding_close_failed` item has preserved investor reservations and an urgent operations task. Fix its cause in Loans. Automatic retries preserve the published outcome; a qualified close cannot be replaced by cancellation.
- 15

Queue tab: Servicing due (Servicing) Borrower repayments (installments) that fall due inside the look-ahead window. Servicing means managing a live loan's repayments. Computed by checking each funded/late loan's repayment schedule against the due window; the amount shown is the outstanding amount on that installment. Handle in Loans (Manage on the loan row > Record borrower repayment).
- 16

Queue tab: Loan risk (Servicing) Loans that are in trouble and need notes, a status review, or recovery work. Populated from loans in status `late`, `defaulted` or `written_off`. Use this to drive recovery actions and public risk notes in the Loans module.
- 17

Queue tab: Secondary approvals (Marketplace) Listings on the secondary market (where investors sell loan holdings to each other) that are non-performing or non-standard and therefore need staff approval before they can go live. Populated from secondary listings in status `'approval_requested'`. Approve, reject or remove them in the Loans module.
- 18

Queue tab: FX settlement (Finance) Internal currency exchanges (FX = foreign exchange) that have happened on the platform but have not yet been declared as settled with the external bank. Populated from FX exchanges that have no settlement link yet, grouped by the currency pair (e.g. CHF/EUR). Declare settlement in Finance ops.
- 19

Queue tab: Failed emails (Comms) Transactional emails that failed to send and were 'dead-lettered' (set aside after exhausting retries) and now need an operator to review. Populated from outbox messages on email topics with status `'dead_letter'`. The detail drawer shows the topic, attempt count and last error.
- 20

Queue tab: Reconciliation breaks (Finance) Mismatches found when comparing the platform ledger against the bank, plus sign anomalies and investor-balance integrity breaks. A 'break' means the numbers do not tie out and must be explained or corrected. Populated from reconciliation snapshots that carry a break signal. This queue has a special Create tasks button (see notes).
- 21

Row title button - opens the detail drawer The bold item title in the Item column doubles as a button. Clicking it (or anywhere on the row) opens a right-side detail drawer with the item's full context: kind, linked object, due date, amount, and metadata. A normal or forced withdrawal drawer additionally shows booking date, value date, collection account, admin note, Finalize withdrawal, and Cancel before execution. Other queue drawers remain contextual and route you to their owning module.
- 22

Selected-queue 'open' count chip The chip near the queue title showing how many items are currently in the selected queue ('2 open' here). It turns informational (blue) when there are items and neutral (grey) when the queue is empty. It mirrors the count badge on the active tab.
- 23

Status chip on a row (Open) Example of a per-row status chip in the Status column. 'Open' here is the state of an admin task. Each row carries its own status; the chip colour follows the status-colour rules described for the Status column.
- 24

Priority chip on a row (High) Example of a per-row priority chip in the Priority column. 'High' renders amber. Rows are not sorted by priority in the table, so scan the colours to find the ones to do first.
- 25

Priority chip on a row (Urgent) Example of an 'Urgent' priority chip, which renders red. Urgent and critical are the most pressing; combined with an overdue due date, treat these as do-now.

NOTES & RULES

- The dashboard is primarily triage. Withdrawal and forced-withdrawal drawers are actionable; finalize only after the external bank transfer has executed, or cancel before execution to release the reserved balance. Other rows still route to Compliance, Finance ops, Loans, Reports, Settings, or Tasks.
- Each queue shows at most a limited number of rows (a per-queue cap). If a queue is busier than that cap, the table is a sample of the most relevant items, not the complete list; use the bottom currency summary and module screens for totals.
- Overdue highlighting: a row is flagged overdue when its due date is before the dashboard's as-of date and its status is not completed, finalized or settled.
- A Refresh button (top right of the queues area) reloads all queues and counts. When the Reconciliation breaks queue is selected, an extra 'Create tasks' button appears: it scans current reconciliation break snapshots and creates an admin task for each one that does not already have one, reporting how many were created versus already existed. It does not create duplicates.
- The empty state ('No items in this queue') simply means the dashboard API returned no active work for that queue right now - it is not an error.

Figure 3.3 The platform balance summary table, one row per currency.

A platform-wide money snapshot broken down by currency. Each row is one currency (for example CHF, EUR) and the columns split that currency's balances into operational buckets - how much is usable, how much is locked, how much is overdue, and how much is tied up in pending bank, withdrawal or FX operations. All amounts are read-only; they are computed from the ledger when the dashboard loads.

1	CURRENCY	AVAILABLE	INVESTABLE	WITHDRAW-ONLY	OVERDUE	FROZEN	PENALTY	PENDING WITHDRAWALS	PENDING BANK OPS	FX UNSETT	6
2	CHF	CHF	CHF	CHF	CHF	CHF	CHF	CHF	CHF	Sold CHF	7
3		984'220.00	838'620.00	0.00	87'100.00	31'500.00	27'000.00	153'000.00	506'000.00	440'000.00	8
4										Bought CHF	9
5										Fee CHF 6:	10
11	EUR	EUR	EUR	EUR	EUR	EUR	EUR	EUR	EUR	Sold EUR 0	
12		641'800.00	574'400.00	0.00	47'000.00	20'400.00	0.00	84'400.00	278'000.00	461'900.00	
										Bought EUR	
										Fee EUR 47	

- 1

Column: Currency The currency code for this row (e.g. CHF, EUR), shown as a chip. Every other number in the row is expressed in this currency. Rows are sorted alphabetically by currency code.

- 2

Column: Available The total unconsumed investor balance in this currency across all balance lots (a 'lot' is a tracked chunk of deposited funds), including frozen and penalty-mode amounts. The balance bucket columns explain what can be done with this money. It is not the amount eligible for a particular loan.
- 3

Column: Investable The portion of Available that is before its holding deadline. This is a potential investment balance; each loan's remaining funding window is checked separately before reservation.
- 4

Column: Withdraw-only A compatibility bucket, normally zero. The current policy does not make money withdraw-only at day 30: investment eligibility depends on the remaining funding window. At day 60, uninvested sources enter the overdue return process.
- 5

Column: Overdue The portion of Available that is already past its 60-day withdrawal deadline and must be returned to the investor. These lots feed the Balance ageing queue. Why it matters: leaving funds here past deadline is a compliance breach - return them.
- 6

Column: Frozen Money in balance lots whose status is 'frozen' (held, not spendable - for example pending a compliance hold). It is part of the platform's holdings but cannot be invested or withdrawn until unfrozen.
- 7

Column: Penalty Money in lots in 'penalty mode' - typically because the investor has no usable payout IBAN, so the funds cannot be returned automatically. These lots also appear in the Balance ageing queue and need operator follow-up to obtain valid payout details.
- 8

Column: Pending withdrawals The total value of investor withdrawals in this currency that have been requested but not yet paid out. This figure combines normal pending withdrawals and forced (day-60 return) withdrawals into a single number. It matches the Withdrawals and Forced withdrawals queues.
- 9

Column: Pending bank ops The total value of bank operations in this currency still in exception state (pending_review or unmatched) - money stuck in the bank-matching step. Mirrors the Bank exceptions queue. Why it matters: until these clear, the related deposits or payouts cannot complete.
- 10

Column: FX unsettled Internal FX activity in this currency not yet settled with the external bank, shown as three stacked lines: Sold (amount sold out of this currency), Bought (gross amount bought into it) and Fee. Mirrors the FX settlement queue. Declare settlement in Finance ops to clear these.
- 11

Currency row value: CHF Example currency row chip for Swiss francs. Read across this row to see CHF's full money position. CHF is typically the platform's primary operating currency.
- 12

Currency row value: EUR Example currency row chip for euros. Read across this row to see EUR's position. A separate row appears for each currency the platform holds balances in.

NOTES & RULES

- Available includes Investable + Withdraw-only + Overdue + Frozen + Penalty. Frozen and Penalty are not investable; each potential investment also requires source coverage through the loan's final subscription date.
- All figures here are derived snapshots, refreshed with the dashboard. You cannot edit them on this screen - to change a balance you act in Finance ops.
- If the table shows 'No currency summaries', the backend has not yet returned currency-level data; press Refresh.
- Amounts are stored internally in minor units (e.g. cents/rappen) and displayed formatted in each currency.

Tasks

The Tasks screen is the operations team's shared to-do list. A "task" is one piece of work an admin needs to do, for example "resolve an unmatched bank deposit" or "review a KYC case". KYC means Know Your Customer: the legal checks that confirm who a person is before they can use a financial service. The screen lets you create tasks, sort through them, and move each one along until it is finished.

Tasks come from two places. Most are created by hand by an admin (the New task button). Some are created automatically by the system, including reconciliation-break tasks and payout-IBAN verification requests. A payout-verification task is linked to the exact InvestorPayoutInstruction the investor asked Garanta to review; verifying that IBAN in Finance Operations resolves the linked task.

Each task has a Type, a Priority (how urgent), a Status (where it is in its life), an optional Due date, and an optional link to a real object in the system (a loan, an investor, a withdrawal, and so on). You can link a task to that object so anyone reading it knows exactly what it is about.

Important: this screen is a lightweight tracker only. It does not perform the actual money or compliance actions. The real work (executing a withdrawal, approving a loan, recording a KYC decision) is done on the owning screen (Finance ops, Loans, Compliance). A task is just a reminder and an audit trail that the work happened.

WHAT YOU DO ON THIS SCREEN

- Create a new internal task with a title, type, priority, optional due date, notes, and an optional link to a real object.
- Filter the task list by status, priority, or type, and free-text search across title, notes, and object id.
- Open any task to see its full detail, edit its fields, and read its event history.
- Move a task through its statuses (Open, In progress, Waiting, Resolved, Cancelled) using quick-action buttons.
- Tell apart manually-created tasks from auto-generated ones (such as reconciliation breaks) by their Type and linked object.
- Record a completion note when you resolve or cancel a task, so the reason is captured permanently.

Figure 4.1 The toolbar at the top of the Tasks screen.

The header bar for the whole screen. It names the queue, and holds the two main action buttons: refresh the list, and create a new task.

1

Operational task queue

Filter, create and update simple admin tasks. Detailed module actions remain in their owning screens.

2

Refresh

3

New task

1

Screen title The name of this screen. "Operational task queue" means the running list of work items the ops team needs to handle. Below it, the subtitle reminds you that detailed module actions (executing money, approving loans) still happen on their own screens, not here.

2

Refresh button Reloads the task list from the server so you see the latest tasks and any changes other admins made. It does not change any data. Use it after someone else has added or updated a task.

3

New task button Opens the "New admin task" form in a pop-up window. This is how you create a task by hand. A title is required; everything else has a sensible default. See the New task notes below for the fields.

NOTES & RULES

- The New task form (opened by this button) asks for: Title (required, up to 255 characters); Type (defaults to "Other"); Priority (defaults to "Normal"); Due at (optional date and time); Related object type and Related object (optional link to a real record); and Notes (free text for context or evidence references).
- Task types available include KYC manual review, Account access review, Borrower onboarding, Loan setup, Payment reconciliation, Payout instruction verification, FX settlement, Document review, Email delivery failure, Reporting, Support, and Other. Payout-verification tasks are normally created automatically from the investor request rather than by hand.
- Gotcha: the system will block you from creating a second Payment reconciliation task that points at the same reconciliation snapshot. This stops duplicate reconciliation-break tasks. Other types have no such uniqueness rule.

Figure 4.2 The filter bar: narrow the task list down to what you care about.

Four controls that filter the table below. Status, Priority, and Type are dropdowns sent to the server; Search is a free-text box that filters the already-loaded list on your screen.

2

Status

5

All statuses

6

Priority

All priorities

Type

All types

3

Search

4

Title, notes, object id

7

- 1

Status field label Labels the Status dropdown. Status is where a task sits in its life cycle (Open, In progress, Waiting, Resolved, Cancelled).
- 2

Priority field label Labels the Priority dropdown. Priority is how urgent the task is (Low, Normal, High, Urgent).
- 3

Type field label Labels the Type dropdown. Type is the kind of work (for example KYC manual review or Payment reconciliation).
- 4

Search field label Labels the Search box. Search looks across each task's title, notes, related object type, related object id, type, status, and priority.
- 5

Status dropdown Choose one status to show only tasks in that state, or leave it on "All statuses" to show every status. The options are Open, In Progress, Waiting, Resolved, and Cancelled. This filter is applied by the server, so the list reloads when you change it.
- 6

Priority dropdown Choose one priority to show only tasks at that urgency, or "All priorities" for every level. The options are Low, Normal, High, and Urgent. Urgent and High are the ones to clear first; the KPI tiles at the top of the screen count urgent open tasks for you.
- 7

Type dropdown Choose one task type to show only that kind of work, or "All types" for everything. This is the quickest way to separate auto-generated tasks (for example Payment Reconciliation or Email Delivery Failure) from manual ones.

NOTES & RULES

- Status, Priority, and Type are independent: setting more than one narrows the list further (a task must match all of them).
- The Search box (not captured as a separate item here) filters only what is already loaded on screen, so it does not fetch more tasks from the server. If a task is hidden by the Status, Priority, or Type dropdowns, searching will not bring it back.
- There is no Apply button; filters take effect the moment you change them. To go back to the full list, set each dropdown back to its "All" option and clear the search box.

Figure 4.3 The task table: one row per task, click a row to open it.

The list of tasks that match the current filters. Each row shows the task title and type, its status and priority chips, due date, linked object, and when it was last changed. Clicking anywhere on a row opens that task's detail drawer.

3	12	TASK	STATUS	PRIORITY	DUE	RELATED OBJECT	UPDATED	4
13		Resolve unmatched CHF lender deposit reference PAYMENT RECONCILIATION	Open	Urgent	05 Jun 2026, 11:30	BANK_OPERATION bank-op-774	05 Jun 2026, 09:15	5
7		PEP flag requires Garanta AML officer decision KYC MANUAL REVIEW	In Progress	Urgent	05 Jun 2026, 12:00	KYC_CASE kyc-case-483	05 Jun 2026, 09:05	6
14		Declare CHF/EUR external FX settlement FX SETTLEMENT	Waiting	High	05 Jun 2026, 17:00	FX_SETTLEMENT_WINDOW 2026-06-05:CHF-EUR	05 Jun 2026, 10:00

15		Dead-lettered installment notification EMAIL DELIVERY FAILURE	Resolved	Normal	05 Jun 2026, 10:00	OUTBOX_MESSAGE outbox-771	05 Jun 2026, 10:21	
9								
10								
11								

- 1

Task column Shows the task title in bold and the task type underneath it. The title is the short description of the work; the type tells you what category it belongs to. Click the row to open the full task.
- 2

Status column Shows the task's current status as a coloured chip. Open and In Progress mean the work is still live; Resolved (done) and Cancelled (dropped) are "terminal" statuses, meaning the task is finished and no longer counts as open.
- 3

Priority column Shows the urgency as a coloured chip: Urgent is red, High is amber, Normal is blue, Low is grey. Work the red and amber ones first.
- 4

Due column The date and time the task is meant to be done by, if one was set. Blank when no due date exists. The "Due today" KPI tile counts non-finished tasks due today, measured on the Europe/Zurich business day.
- 5

Related object column Shows the type of record this task is linked to (for example Loan or InvestorWithdrawalRequest) and its id underneath. A dash means the task is not linked to any record. Use this to jump to the right screen to do the actual work.
- 6

Updated column When the task was last changed. Useful for spotting stale tasks that no one has touched in a while.
- 7

Task row: Payment Reconciliation (Urgent, Open) An example row. The title is "Resolve unmatched CHF lender deposit reference" and the type is Payment Reconciliation. This type is typically auto-generated by the daily reconciliation sync when bank and ledger figures disagree. Click it to open the task and see which reconciliation snapshot it is linked to.
- 8

Task row: KYC Manual Review (Urgent, In Progress) An example row, "PEP flag requires Garanta AML officer decision". PEP means Politically Exposed Person, someone in or close to public office who needs extra anti-money-laundering (AML) scrutiny. "In Progress" means an admin has started it. The real decision is recorded on the Compliance screen; this task just tracks that it needs doing.
- 9

Task row: FX Settlement (Waiting, High) An example row, "Declare CHF/EUR external FX settlement". FX means foreign exchange (swapping one currency for another). "Waiting" means the task is paused, usually blocked on someone or something outside the team. The actual settlement is declared on the Finance ops screen.
- 10

Task row: Document Review (Open, Normal) An example row, "Review revised primary-market risk acknowledgement template". The "primary market" is where investors fund brand-new loans (as opposed to the secondary market, where they buy and sell existing loan pieces). This task is a normal-priority review item still open.
- 11

Task row: Email Delivery Failure (Resolved, Normal) An example row, "Dead-lettered installment notification". "Dead-lettered" means an email that could not be delivered and was set aside. This task type is usually auto-generated. Its status is Resolved, so it is finished; resolved tasks stay in the list for the record but no longer count as open.
- 12

Status chip: Open (first row) The status chip for the first row. Open is the starting state of every new task, meaning no one has begun it yet.
- 13

Priority chip: Urgent (first row) The priority chip for the first row. Urgent (red) is the highest level and should be cleared first.

- 14

Status chip: In Progress (second row) In Progress means an admin has picked the task up and is actively working it. Set it from the task drawer using the "Mark in progress" button.
- 15

Status chip: Waiting (third row) Waiting means the task is paused, typically blocked on an external party or a dependency. It still counts as open (not finished). Set it with the "Waiting" button in the task drawer.
- 16

Status chip: Resolved (fifth row) Resolved is a terminal (finished) status meaning the work was completed successfully. Setting it stamps a completion time and reveals a Completion note box to record how it was resolved.

NOTES & RULES

- Clicking any row opens the task detail drawer on the right. There you can edit Title, Type, Priority, Status, Due at, and Notes, then press "Save changes".
- Status transitions: there are no locked-down rules on which status can follow which. You can move a task to any of the five statuses at any time. The two finished states are Resolved (done well) and Cancelled (dropped); the system marks both as terminal.
- Quick-action buttons in the drawer let you jump straight to a status without saving the whole form: "Mark in progress", "Waiting", "Resolve", and "Cancel task". Each one saves immediately and writes an entry to the event history.
- Gotcha: when you set a task to Resolved or Cancelled, the system records the completion time and shows a Completion note field. If you later move the task back to a non-terminal status (Open, In progress, or Waiting), the system automatically clears both the completion time and the completion note. Re-opening a finished task therefore loses its recorded completion reason.
- Every create and every change is written to an append-only event history shown at the bottom of the task drawer. "Append-only" means entries can be added but never edited or deleted, so it is reliable evidence of who did what and when. Each entry shows the event type, the time, any note, and the status change (for example Open to In Progress) and who made it.
- If the table shows "No tasks match these filters", either no tasks exist yet or your filters are too narrow. Loosen the dropdowns or clear the search box.

Users

This screen is the account directory for the whole platform. Every account that exists on BANXUM appears here: investors (lenders), legal-entity lender representatives, admin staff, and superadmins.

It answers the everyday support questions: does this person have an account, what state is it in, is their phone verified, what documents have they accepted, and what may they currently do? It is also where account-level decisions are made - creating admin staff, restricting or closing accounts, and opening a read-only view of an investor's portal.

Everything you do here is audited. Account actions are the most sensitive tools in the console: they change what a real person can do with their money. The console records who did what, to whom, and why.

One important thing this screen does not do: it never shows or edits money. Balances, deposits and withdrawals live in Finance operations. This screen is about identity, access and evidence.

WHAT YOU DO ON THIS SCREEN

- Look up any account by name, email, investor reference or UUID, and filter by account type or status.
- Create new admin staff accounts (superadmin only). There is no self-service admin signup and no 'forgot password' - a superadmin creates the account and resets passwords.
- Open 'Access controls' on an account to restrict, lock, reactivate or close it, with a reason code, a note, and an evidence summary. Closing requires confirming the account is clean (empty).
- Open 'Documents' to see every legal document a user has accepted (agreement versions, timestamps) and generate the evidence PDF or CSV.
- Start a 'Read-only view' of an investor account (superadmin only) to see exactly what that investor sees, without being able to change anything.

Figure 5.1 The user directory: search, filters, and per-account actions.

One table for every platform account. The search box matches name, email, investor reference or UUID as you type. Each row shows who the account belongs to, what kind of account it is, its current standing, and three action buttons. The list is paginated - use Previous/Next to move through pages.

13

14

- 1

User accounts heading The directory card. The description under the title reminds you that account-level actions taken here are audited.
- 2

Name column The person's registered full name. For admin staff this is the name the superadmin entered when creating the account.
- 3

Email column The account's login email. Investors sign in with magic links sent to this address; admins receive their one-time login codes here. If a user reports missing emails, check they are looking at this exact mailbox.
- 4

Reference column The investor reference - the short permanent code (starting with L) used in deposit payment references such as BX-CHF-L4F8K2Q9R. Staff accounts have no reference because they never hold money.
- 5

Status column The account's standing: Pending KYC (registered but not yet verified), Active (normal use), Restricted (limited while under review), Locked (cannot sign in or act), Closed (permanently ended). Restricted and Locked both block financial actions.
- 6

Phone verification column Whether the mandatory SMS phone verification is complete. An investor without a verified phone cannot reach the financial parts of the portal, even if their email works.
- 7

Account type filter Narrow the list to one kind of account: natural-person lenders, legal-entity lender representatives, admins, or superadmins.
- 8

Account status filter Narrow the list to one standing, for example all Restricted accounts when reviewing open compliance holds.
- 9

Create admin button Superadmin only. Opens the form to create a new staff account: email, full name, role (admin or superadmin) and an initial password. Admins sign in with email + password + an emailed one-time code. There is no self-service password reset - only a superadmin can set a new password.
- 10

Access controls (row action) Opens the account-access form for that user. You choose a new status (Active, Restricted, Locked or Closed), pick a reason code, and write an admin note plus an evidence summary. Closing an account additionally requires ticking the clean/empty-account confirmation - the attestation that you checked the balance is zero. Every change lands in the audit trail.
- 11

Documents (row action) Opens the user's accepted-document history: which agreement versions they accepted, when, and in what context (registration, an investment order, a secondary-market trade). From here you can generate the evidence PDF or CSV that reproduces exactly what was accepted - useful for support questions and audits.
- 12

Read-only view (row action) Superadmin only, and only for non-staff accounts. Opens the investor portal in a new tab exactly as that investor sees it - same dashboard, balances, portfolio and documents - but every change attempt is rejected: it is strictly read-only. Access uses a short-lived signed token (about 30 minutes) tied to your own superadmin session, and every start is recorded as a high-risk audit event. Admin and superadmin accounts can never be viewed this way.
- 13

Previous page The directory is paginated. Use Previous/Next to page through accounts; the search and filters apply across all pages.

NOTES & RULES

- Every action on this screen is audit-logged with actor, target, reason and timestamp. Assume everything you do here will be reviewed.
- Restricted and Locked accounts cannot sign in or move money; use Restricted while investigating and Locked for hard blocks.
- Account closure is only for clean (empty) accounts - the form makes you confirm you checked. Financial records, documents and the audit trail are always retained.
- Read-only views exist so support can see what an investor sees without asking for screenshots. They cannot click, submit, or change anything on the investor's behalf.
- There is no impersonation with write access anywhere on the platform, and no way to view another admin's account.

Compliance

Compliance is where Garanta staff make the identity and money-laundering decisions that an automated check could not finish on its own.

Some background terms, in plain language. KYC means "Know Your Customer": proving a person really is who they say they are. KYB is the same idea for a business ("Know Your Business"). AML means "Anti-Money-Laundering": checking that a customer is not on a sanctions list, is not a known criminal, and is not trying to hide where their money came from.

BANXUM does not run these checks by hand. An outside provider called Didit collects the customer's ID documents and screens them. Didit then returns a result. Most results are automatic: clearly approved, or clearly declined. But some results are unclear and Didit "routes them to manual review", which means it hands the case to a Garanta officer to decide. Those cases land on this screen.

A "PEP" is a Politically Exposed Person: someone in a powerful public role (or close to one), who is treated as higher-risk. "Adverse media" means bad news coverage linking the person to crime or wrongdoing. "Sanctions" are official government blocklists; a person on one is legally forbidden to do business.

The second half of this screen is unrelated to KYC: it lets an admin change a user's account status, for example to freeze a suspicious account or close one on request.

WHAT YOU DO ON THIS SCREEN

- Read the cases Didit sent to manual review and see why each was flagged (PEP, high risk, adverse media, and so on).
- Record an AML decision on a selected case: approve it, decline it, ask the customer to re-verify, or reopen it for further review.
- Change a user account's status: restrict, lock, close, or reactivate it, always with a reason and a note.
- Understand the hard limits the system enforces for you: sanctions hits and provider declines can never be approved by hand, closing an account needs a clean-account confirmation, and only a superadmin may touch another admin's account.

Figure 6.1 KYC manual review queue

A table of identity/AML cases that Didit could not decide automatically and handed to Garanta. Each row is one subject (a person or business). Click a row to load that case into the decision form on the right. The text below the table notes the key rule: sanctions and fraud blocks stay non-overridable on the server, so this queue is for the genuinely judgeable cases.

KYC manual review

Review KYC/KYB cases routed to Garanta manual review. Click a row to load it into the AML decision panel below. Sanctions and fraud blocks remain non-overridable server-side.

Showing 1-10 of 12

PreviousPage 1 of 2Next

- 1

KYC manual review (panel title) This card lists every case the Dudit provider routed to manual review. A case appears here only when the automated check was inconclusive or flagged a risk that a human must judge. If nothing is here, no case currently needs a decision.
- 2

Email column The account's login email - the fastest way to match a case to a support conversation.
- 3

Refresh button Re-fetches the queue from the backend so you see the latest cases. New cases arrive when Dudit finishes screening a customer and decides a human is needed. Click this if you are waiting on a case to come through.
- 4

Name column The person's registered name, so you can recognize the case without decoding IDs. Click any row to load this case into the decision form below.
- 5

Status column The current KYC outcome for that subject, shown as a coloured chip. Possible review statuses include Manual review, High risk, PEP hit, Adverse media hit, and (non-decidable here) Sanctions hit and Declined. The status drives what you are allowed to do: only review-routed statuses can be manually approved.
- 6

Risk column Dudit's overall risk classification for the subject, such as High. It is a quick read of how concerning the provider found the case before you open it.
- 7

Flags column The specific reasons the case was flagged, each as a small chip. Examples: PEP (a politically exposed person), High risk, Adverse media (bad press), Sanctions, Identity fraud. A row can carry several flags at once. These tell you what to look into before deciding.
- 8

Reference column The investor reference (the short L-code also used in deposit payment references). Provider session/report references moved to the selected-case detail card in the decision form below.
- 9

Updated column When the case last changed, as a date and time. Helps you work the oldest pending cases first and confirm a case reflects the provider's most recent result.
- 10

PEP Hit status chip (example row) A status chip reading "PEP hit" means the provider matched this subject to a politically exposed person. PEP is a review-routed status, so you can still approve it by hand after reviewing the evidence, unlike a sanctions hit. Click the row to load it into the decision form.
- 11

Adverse Media Hit chip (example row) "Adverse media hit" means the provider found negative news linking the subject to wrongdoing. Like PEP and High risk, this is decidable here: after reviewing the evidence you can approve, decline, request re-verification, or reopen the case.
- 12

Previous / Next (pagination) The review queue shows up to 10 cases per page. Use Previous/Next to move through the queue; the count above the table shows where you are.

NOTES & RULES

- Clicking any row selects that case. The selected row is highlighted and its ID is copied into the "Record AML decision" form to the right, so you decide on the case you are looking at.
- Sanctions hits and confirmed-fraud declines are never decidable from this screen. The backend refuses to manually approve them no matter what you submit; this queue only safely holds judgeable statuses (Manual review, High risk, PEP hit, Adverse media hit).
- In preview/demo mode the cases shown are dummy Dudit status mappings. In live mode the screen reads only real KYC evidence owned by the backend.

Figure 6.2 Record AML decision form

The form where you record your decision on one KYC/AML case. Pick the case (it auto-fills from the row you clicked), choose the decision and a reason, write a note plus an evidence summary, then submit. The backend re-checks every rule before saving, and the decision is permanently audit-logged.

Record AML decision

Select the case, review the person's details below, then record the decision. The backend enforces allowed status transitions.

9

- 1

Record AML decision (form title) Use this form only after you have reviewed Didi's evidence for the case. The note under the title is a reminder: the backend enforces which status changes are allowed, so an invalid decision is rejected rather than silently applied.
- 2

KYC case (lookup field) Identifies which case you are deciding. It auto-fills when you click a row in the queue, but you can also type to search for a case. Required. The decision is applied to exactly this case.
- 3

Decision (dropdown) What you are deciding. Approve clears the subject (only allowed from a review-routed status, never from a sanctions hit or a provider decline). Decline rejects them. Request re-verification asks the customer to redo their checks. Reopen sends the case back into manual review for another look.
- 4

Decision options (Approve / Decline / Request Reverification / Reopen) These are the four selectable decisions. Each maps to a fixed result on the backend: Approve sets the case to Approved (and activates the user if they were waiting on KYC), Decline sets Declined, Request re-verification sets Re-verification required, and Reopen returns it to Manual review.
- 5

Reason code (dropdown) The compliance reason for your decision, recorded for audit. Options include PEP review, High-risk review, Adverse-media review, Sanctions review, Provider decline review, Inconclusive provider result, Document or identity issue, Re-verification required, Off-platform review, Admin correction, and Other. Pick the one that matches why you decided.
- 6

Officer note A free-text note explaining your reasoning. You must fill in either this note or the evidence summary; the backend rejects a decision with both left blank. Keep it specific and factual.
- 7

Evidence summary A short summary of the provider evidence you relied on. Counts as the required justification if the officer note is empty. Together with the note it forms the permanent record of why this case was decided.
- 8

Submit KYC decision button Sends the decision. The backend re-confirms you are an active admin, that a note or evidence is present, and that the status change is allowed. If it passes, the case status is updated, the decision is written to the audit trail, and you see a confirmation. If it fails (for example trying to approve a sanctions hit), it is refused with an error.
- 9

Selected-case flags (detail card) When you pick a case, a detail card shows the person's data and the exact provider flags (for example PEP or High risk) plus provider references - the context you need to decide without leaving the form.

NOTES & RULES

- Approve is the most restricted choice. It only works when the case is in a review-routed status (Manual review, High risk, PEP hit, or Adverse media hit). It is impossible to approve a Sanctions hit or a Declined case; the server blocks it.
- Every submitted decision is recorded permanently: who decided, the previous and new status, the reason code, and your note/evidence. These records are kept for audit and are not deletable.
- In preview/demo mode the form only shows a preview message and does not change any real case.

Finance Operations

Finance Operations is the money-movement cockpit of the admin console. It starts with Pending finance operations, a bounded working list that combines unresolved finance tasks with bank exceptions, withdrawals, forced withdrawals, FX settlement items, and reconciliation breaks. Below that, Garanta staff record cash that has actually entered or left the company's bank account and keep the internal ledger in step with reality. Most forms record a bank transfer that you (or the bank) already arranged or observed; the live balance-ageing scan is the exception because it can create forced withdrawals and post penalty charges.

A few terms you will see on every form. 'Minor units' means the amount in the smallest currency unit, i.e. cents (rappen for CHF). So 2,500,000 minor units equals 25,000.00 CHF. Always enter whole numbers in minor units, never decimals. The 'collection account' is Garanta's own pooled bank account that holds all lender money before it is invested or paid out. Launch collection accounts are Garanta_CHF (IBAN CH1183019GARANTAFI001, QR IBAN CH8330334GARANTAFI001, BIC YAPECHZ2) and Garanta_EUR (IBAN CH8183019GARANTAFI002, BIC YAPECHZ2). A 'deposit' is incoming money from an investor; a 'disbursement' is outgoing money to a borrower; a 'withdrawal' is outgoing money back to an investor.

Most forms include an 'investor' (or loan/borrower/withdrawal) autocomplete. You type a name, email, investor reference (a code like L7K3M9PQ2), UUID, or IBAN; the box searches the database and lets you pick a real record. When you pick one, the box quietly stores the matching hidden ID and shows 'Selected ID: ...'. If you type text but never pick a result, the form will refuse to submit. The visible text is just for searching; the hidden ID is what actually gets sent.

Because each action posts permanent accounting entries, every submit carries an automatic idempotency key so an accidental double-click cannot double-book a transfer. Watch the success and error banners after each action: they tell you exactly what the ledger did.

Activated Loan Originator subscription principal and the originator share of borrower repayments accrue in separate originator-payable accounts. The Originator settlement queue groups unsettled items by originator and currency, shows the payable and oldest age, and lets an admin record the complete external bank settlement. A task becomes due at day 3; the oldest item must not pass day 5.

WHAT YOU DO ON THIS SCREEN

- Start with the pending finance-operations table and open the relevant action or owning module for each unresolved item.
- Declare a matched incoming lender deposit and credit it to the investor's balance.
- Review and add verified payout IBANs without removing verified accounts already established by deposits.
- Look up an investor's ledger balance broken into investable, withdraw-only, overdue, frozen and penalty buckets.
- Run the balance ageing scan that fires 60-day holding reminders, forced withdrawals, and penalty charges (with a safe dry-run mode).
- Create a reconciliation snapshot that compares the bank's stated balance against what the ledger expects.
- Finalize or cancel investor withdrawals, finalize direct borrower loan disbursements, declare external FX settlements, and settle complete Loan Originator payable batches after the bank transfer executes.

Figure 7.1 Pending finance operations: start the day from one consolidated work list.

This table combines unresolved finance tasks with actionable bank-operation, withdrawal, forced-withdrawal, FX-settlement, and reconciliation queues. It is a triage surface: resolve withdrawals here, and use the named owning module for the other work types.

- 1

Work item The human-readable task or queue title. The smaller line identifies the underlying work type. Payout-IBAN verification requests created by investors appear here as finance tasks.
- 2

Status Current workflow state, such as Open, Waiting, Pending review, Requested, Unsettled, Break, or Integrity break. Terminal admin tasks are excluded from this table.
- 3

Due Task due timestamp or queue due date. A dash means the source queue has no separate deadline.
- 4

Action Withdrawals expose Resolve here and prefill the execution form below. Other items state which dashboard or owning module to open.
- 5

Resolve withdrawal Scrolls to Withdrawal execution with this request selected. Finalize only after the bank transfer executes; cancel only before execution.

NOTES & RULES

- The table is bounded for launch and intentionally does not replace the full Tasks or Daily dashboard screens.
- Investor-requested additional IBANs remain unverified until an admin checks ownership in Payout instruction. Verifying the exact instruction resolves its linked task.
- Normal and forced withdrawals use the same conservation-safe finalize/cancel service. A forced withdrawal is still only requested until its bank payment is finalized.

Figure 7.2 Loan Originator settlement queue: unsettled activation and servicing payables grouped for bank execution.

This queue groups amounts owed to each Loan Originator by currency. It keeps activated subscription principal and the originator share of later borrower repayments separate from investor liabilities and gives operations a single settlement surface.

1

Loan Originator settlement queue

Purchase proceeds and servicing proceeds accrue separately, then settle in an evidenced batch within five calendar days.

No Loan Originator payables

Purchase and servicing payables awaiting batch settlement appear here.

Refresh

2

- 1

Loan Originator settlement queue Review each grouped originator/currency payable before executing its external bank transfer. The operational due date is day 3 and the oldest unsettled item must not pass day 5.
- 2

Refresh Reloads unsettled originator activation and servicing payables after a settlement or a newly reconciled payment.

- Settlement clears complete evidence-backed payable items; do not enter an arbitrary partial allocation.
- Borrower repayments feeding this queue use the same universal payment order as every other loan: Garanta legal costs and recovery fee, penalty, interest, then principal.

Figure 7.3

This form declares that money from an investor has landed in Garanta's collection account, credits that investor's balance, and establishes the checksum-valid source IBAN from the bank statement as a verified payout account. Use it only when a real incoming transfer has been seen on the bank statement.

Lender deposit

Declare a matched incoming transfer. Its valid source IBAN becomes a verified payout account for this investor.

Collection account

BANXUM-CHF-COLLECTION

Payer name

Source IBAN

Required. Spaces are accepted; the server validates the country length and ISO 13616 checksum.

Payment reference

Declare deposit

- Investor (from bank reference)** Identify which investor sent the money. Best practice: paste the bank-statement reference first, because it usually contains the investor's reference code (the form auto-extracts a code shaped like L followed by 8-9 letters/digits). If there is no usable reference, search by payer first name, surname, or email. You must pick a real match from the dropdown; the hidden investor ID is what gets credited. If you only type text and never select, the deposit will not submit.
- Amount minor units** The deposit amount in cents (minor units). Enter 2500000 for 25,000.00 CHF. Must be a positive whole number. This exact amount is credited to the investor and debited into the collection-cash ledger account, so it has to match the bank statement to the cent.
- Currency** Currency code such as CHF or EUR. The currency must be enabled in the system or the deposit is rejected. It must match the currency that actually arrived.
- Booking date** The date the bank booked the transfer. This is recorded on the ledger entry for accounting/reporting; it does not change when the investor's holding clock starts.
- Value date** The date the funds became available (the bank value date). This is the important one: it starts the investor's holding clock. From this date the system sets the 60-day holding deadline; a reservation must cover the loan's remaining funding period on the new balance lot.
- Collection account** Which of Garanta's pooled bank accounts received the money. Pre-filled with the default collection account. Required. The cash is debited into this collection-cash ledger account.
- Payer name** The name on the incoming transfer. Optional, but recording it helps with audit and matching. Tip: if you have not yet identified the investor, typing at least 3 characters here can seed the investor search.
- Source IBAN** Required. Copy the payer IBAN observed on the incoming bank transfer. Spaces are allowed; the service normalizes the value, checks its country-specific length and MOD-97 checksum, and rejects an invalid IBAN before creating any bank operation, ledger entry, balance lot, or payout instruction. A successful declaration verifies this exact investor/currency/IBAN for future payouts.
- Payment reference** The reference text from the bank transfer. Optional. If it contains the investor reference code and you have not yet selected an investor, the form copies that code into the investor search box for you.
- Declare deposit** Submits the deposit. On success it creates a reconciled bank-operation record, posts a balanced ledger entry (debit collection cash, credit the investor's balance liability), opens a new balance lot, and creates or updates that exact source IBAN as an active verified payout instruction in the same transaction.

- Only an active admin can declare a deposit. The chosen account must be a lender account that is not restricted, locked, or closed. A pending-KYC lender may receive a deposit; financial actions remain blocked until onboarding gates pass.

- Figure 7.4** Payout instruction: register the verified IBAN used to pay an investor.

A payout instruction is a saved bank account (IBAN) that Garanta is allowed to send an investor's money to. Deposit source IBANs are verified automatically. Use this form when an investor requests another account: verifying it adds that exact IBAN and does not disable their existing verified deposit account.

Payout instruction

Verify an additional IBAN used for withdrawals and day-60 forced returns.
Existing verified IBANs remain usable.

Notes

6

Register payout instruction

☒ IBAN is usable and verified for this investor.

- Investor / payout owner** Search and select the investor who owns this bank account, by name, email, reference, UUID, or IBAN. You must pick a real match; the hidden investor ID is stored. This form also passes the IBAN you type below into the search, so it can warn you if that IBAN already belongs to other investors.
 - Currency** Currency this payout account is for (e.g. CHF). Must be an enabled currency. A separate active instruction exists per currency, so registering a CHF instruction does not touch the investor's EUR instruction.
 - Destination IBAN** The investor's bank account number to pay out to. The system normalizes it (removes spaces and uppercases it), checks the country-specific IBAN length, and verifies the MOD-97 checksum. A structurally plausible but checksum-invalid IBAN is rejected.
 - Account name** The account holder's name as it appears at the bank. Required. Used on the outgoing payment.
 - Notes** Free-text note for context (e.g. why this account was added or how it was verified). Optional.
 - Register payout instruction** Saves or updates this exact investor/currency/IBAN instruction. It is additive: other verified IBANs remain active. If the 'usable and verified' checkbox is ticked, this IBAN is immediately usable for payouts and any linked investor-request verification task is resolved. If unticked, it remains pending and cannot receive withdrawals.

NOTES & RULES

- A checkbox below the fields, 'IBAN is usable and verified for this investor', is ticked by default. Leave it ticked only when you have confirmed the account belongs to the investor.
- GOTCHA - IBAN collision warning: if the IBAN you entered already matches more than one investor in the system, an amber banner 'IBAN matches multiple investors' appears. Review the matches before saving, since paying the wrong person is hard to reverse.
- Different IBANs are additive. Do not disable a verified deposit-source account merely because the investor asks to verify another destination account.
- Only an active admin can register an instruction here. Investors can request another IBAN after an email security code; that request is unverified and automatically opens a linked finance task until an admin verifies it.

- 1

As of timestamp The point in time to evaluate the lots against. Leave blank to use 'now'. You can backdate or set a specific moment for testing or catch-up runs. Reminder days are measured from each lot's value date up to this timestamp.
- 2

Currency filter Optional. Limit the scan to one currency (e.g. CHF). Leave blank to scan all enabled currencies at once.
- 3

Run ageing scan Runs the scan. The success banner reports how many reminders are due and how many forced withdrawals were created. What it does depends entirely on the 'Dry run only' checkbox above the button.

NOTES & RULES

- GOTCHA - Dry run: a 'Dry run only' checkbox is TICKED by default. With dry run on, the scan only reports what WOULD happen (reminders, forced-withdrawal candidates, penalty-mode transitions) and changes nothing. Untick it to actually send reminders, create forced withdrawals, flip lots into penalty mode, and post penalty charges. Always dry-run first.
- Reminders fire on holding days 25, 46, 53, 58, 59 and 60; each reminder is only sent once per lot.
- At or after the 60-day withdrawal deadline: if the investor HAS an active verified payout instruction, the scan auto-creates a forced withdrawal for the overdue amount to that IBAN. If they do NOT, the lot is moved into penalty mode and a daily penalty is charged against the balance instead. Penalty-mode balances also block FX exchanges and secondary-market purchases until a usable payout path resolves the overdue money.
- Only an active admin can run the scan. A live run posts real ledger entries and emails, so treat it like any other money-moving action.

Figure 7.7 **Reconciliation snapshot: compare the bank's balance to what the ledger expects.**

A 'reconciliation snapshot' is a point-in-time check that the real bank balance matches the sum of everything the ledger says Garanta owes and holds (investor balances, payables, accrued revenue, FX clearing, suspense, plus any pending exceptions you note). It records the difference and raises alerts if anything is off.

1

4

Pending exceptions minor

0

5

Notes

6

Create snapshot

Formatted amount: CHF 1'000'000.00

Formatted amount: CHF 0.00

- 1

Currency Which currency to reconcile (e.g. CHF). Must be an enabled currency. Each currency is reconciled separately because each has its own bank balance and ledger accounts.
- 2

As-of date An admin-chosen label for which day this reconciliation represents (e.g. month-end). Note: the figures are computed from the current ledger state at the moment you create the snapshot; the as-of date is just the reporting label attached to it.
- 3

Bank stated balance minor The balance the bank actually reports for the collection account, in minor units (cents). This is the 'truth' the ledger is checked against. Must be a non-negative whole number.
- 4

Pending exceptions minor In minor units, the amount of known-but-not-yet-booked items (e.g. cash that arrived but is not yet matched). Optional, defaults to 0. It is added to the expected balance so genuinely-pending money does not look like a break.
- 5

Notes Free-text note describing the reconciliation run or explaining a known difference. Optional.
- 6

Create snapshot Computes the expected ledger balance, subtracts it from the bank-stated balance, and saves the snapshot. The success banner shows the resulting difference. A difference of 0 means everything ties out; any non-zero difference is flagged as a reconciliation break.

NOTES & RULES

- Expected balance = investor balance liability + withdrawal payable + borrower disbursement payable + recovery distribution payable + Garanta accrued revenue + FX clearing + suspense + your pending exceptions. Difference = bank stated balance minus expected.
- Creating a snapshot can raise alerts that show up as reconciliation breaks on the dashboard: a non-zero reconciliation difference, a mismatch between the bank balance and the collection-cash ledger, or investor-balance integrity breaks (a lot's available amount not matching its liability posting).
- Only an active admin can create a snapshot. It is a read-then-record operation: it does not move money, but it does permanently store the comparison and may open follow-up tasks.

Figure 7.8 Withdrawal execution: finalize a paid-out withdrawal or cancel one before it leaves.

This form handles an investor withdrawal that the investor already requested. You either finalize it (record that the bank actually paid it and clear the ledger) or cancel it (release the reserved funds back to the investor before the bank sends anything). The lookup only shows withdrawals in requested status. The identical form is also available directly in normal and forced-withdrawal dashboard drawers.

Withdrawal execution

Finalize executed withdrawals or cancel requested withdrawals before bank execution.

1	Requested withdrawal wd-1002 Selected ID: wd-1002	Booking date 05.08.2026	2
3	Value date 05.08.2026	Collection account BANXUM-CHF-COLLECTION	4
Admin note / cancel reason		5	
6	Finalize withdrawal	Cancel before execution	7

- 1 Requested withdrawal** Search and select the pending withdrawal to act on, by lender name, email, reference, withdrawal UUID, or IBAN suffix. The list is pre-filtered to 'requested' withdrawals only. You must pick a real match; the hidden withdrawal ID is what both buttons act on.
- 2 Booking date** Used only when finalizing: the date the bank booked the outgoing payment. Recorded on the ledger entry. Not used by Cancel.
- 3 Value date** Used only when finalizing: the date the funds left the account. Recorded on the outgoing ledger entry. Not used by Cancel.
- 4 Collection account** Used only when finalizing: which Garanta account the money was paid out from. Pre-filled with the default collection account. The cash is credited (reduced) out of this collection-cash account.
- 5 Admin note / Cancel reason** Free text. On Finalize it is stored as the admin note on the withdrawal. On Cancel it is the cancellation reason (if left blank, Cancel uses a default reason). Recommended on cancels so the audit trail explains why.
- 6 Finalize withdrawal** Confirms the bank has executed the payout. It creates a reconciled outgoing bank-operation, posts a ledger entry that clears the investor's withdrawal-payable against collection cash, and marks the withdrawal FINALIZED. Only works on a withdrawal still in 'requested' status; a withdrawal already finalized returns its existing result instead of double-paying.
- 7 Cancel before execution** Reverses a not-yet-paid withdrawal: it restores the reserved funds back to the investor's balance lots and marks the request CANCELLED. Only works while the withdrawal is still 'requested'. Use this when the payout was stopped before the bank sent it. This is a destructive (danger) action, so confirm you have the right request selected.

NOTES & RULES

- Finalize and Cancel are mutually exclusive paths on the same request: finalize records that money LEFT; cancel records that money was returned to the investor and never left.
- Both actions require an active admin and carry an automatic idempotency key, so a repeated click cannot pay or cancel twice.
- If a withdrawal is not in 'requested' status, the matching action is refused (you cannot cancel an already-finalized payout, or finalize a cancelled one).

Figure 7.9 Borrower disbursement: record paying a funded loan out to the borrower.

A 'disbursement' is the outgoing payment of a funded loan to the borrower's bank account. At funding close the FULL accepted principal was moved into the borrower-disbursement payable (no fee accrued at close; the planned fee is evidence only). This form records the payout in the ledger: by default it sends the funded principal minus the BANXUM fee (default 2%), books the fee as Garanta revenue at disbursement, and clears the transfer plus fee against the payable. It only works once the loan is in 'funded' status. The same action is also available from the Loans table via Manage > 'Borrower disbursement'.

Borrower disbursement

Record external payout of an accepted funded loan to the borrower.

1 → Loan loan-zug-park-ii Selected ID: loan-zug-park-ii	2 ← Borrower Helvetic Wohnbau AG Derived borrower ID: borrower-helvetic-wohnbau
3 → Amount minor units 98000000 Formatted amount: CHF 980'000.00	4 ← BANXUM fee minor units 2000000 Formatted amount: CHF 20'000.00
5 → Currency CHF	6 ← Booking date 05.08.2026
7 → Value date 05.08.2026	8 ← Payee name Helvetic Wohnbau AG
9 → Payee account CH3900762011623852957	
10 ← Override note Contract defaults: fee = principal x success-fee bps, amount = principal - fee. A note is required when amounts differ from those defaults. Prefer Loans → Manage → Borrower disbursement for pre-filled defaults.	
11 ← Finalize disbursement	

- 1 Loan** Search and select the loan being disbursed, by title, borrower name, status, or UUID. Picking a loan auto-fills the borrower (and the currency) from that loan, so you do not enter them by hand. Clearing the loan also clears the derived borrower.
- 2 Borrower** Once a loan is selected this becomes a read-only field showing the borrower derived from the loan (with the derived borrower ID in the hint). This is a safety rule: the borrower must match the loan, so the system fills it for you rather than letting you mistype it. If no loan is selected, it becomes a borrower search box instead.
- 3 Amount minor units** The amount to pay the borrower, in cents (minor units). It defaults to the funded principal minus the BANXUM fee (default fee = funded principal x borrower_success_fee_bps, default 2%) and is READONLY together with the fee; overriding them requires changing both together and providing a required explanation note. The transfer is debited against the borrower-disbursement payable and credited out of collection cash.
- 4 BANXUM fee minor units** The platform fee booked as Garanta revenue at disbursement. It defaults from the funded amount and configured success-fee basis points. Amount plus fee must clear the full outstanding borrower-disbursement payable.
- 5 Currency** Currency of the payout. Auto-filled from the selected loan. It must match the loan's currency or the disbursement is rejected.
- 6 Booking date** The date the bank booked the outgoing payment. Recorded on the ledger entry.
- 7 Value date** The date the funds left the account. Recorded on the outgoing ledger entry.
- 8 Payee name** The borrower account holder name the money was sent to. Required.
- 9 Payee account** The borrower bank account the money was sent to. Required.
- 10 Override note** Required when overriding the default transfer/fee split. The override may change that split but the combined amount must still clear the complete outstanding payable.
- 11 Finalize disbursement** Records the disbursement. On success it creates a reconciled outgoing bank-operation, posts the ledger entry clearing the full transfer plus BANXUM fee against the borrower-disbursement payable, and books the fee as Garanta/BANXUM revenue. A residual payable is rejected.

- SAFETY RULES enforced by the system: the loan must be in 'funded' status; the loan's currency must equal the disbursement currency; the selected borrower must match the loan's borrower; the borrower must have no explicit compliance hold or Declined/Manual review decision (company KYB is offline); borrower transfer + fee must exactly clear the outstanding borrower payable; and the fee must be between 0 and 10% of the funded amount. Any of these failing blocks the disbursement.
- The default amount and fee are readonly: overriding them is only possible together and with a required explanation note, which is stored for audit.
- 'KYB' (Know Your Business) is the business equivalent of identity verification for the borrowing company.
- Only an active admin can finalize, and the automatic idempotency key prevents double-paying the borrower on a repeat click.

FX means foreign exchange (swapping one currency for another, e.g. CHF to EUR). When investors convert balances inside the platform, Garanta later settles the net amount with a real bank/broker. This wide panel lets you load two reports for a date range and then declare that external settlement.

- 1 Start date** Start of the date range for the reports and the settlement batch. The reports cover internal exchanges from this date.
- 2 End date** End of the date range. The end date is also used as the booking and value date of the settlement when you declare it. It cannot be before the start date.
- 3 Sold currency** The currency Garanta sold to the external counterparty (e.g. CHF). Must be enabled, and must differ from the bought currency, or the settlement is rejected.
- 4 Bought currency** The currency Garanta received (e.g. EUR). Must be enabled and different from the sold currency. The pair must be an enabled FX pair.
- 5 Sold amount minor** How much of the sold currency actually went out, in minor units (cents). Must be positive. Compared against what internal exchanges expected; the gap is the 'residual' shown in the realized report.
- 6 Bought amount minor** How much of the bought currency actually came in, in minor units. Must be positive. Compared against the expected bought amount to compute the residual.
- 7 Load reports** Fetches both reports for the date range without changing anything. 'Internal delta' shows what investors converted inside the platform; 'Realized settlement' shows the actual bank execution and residuals. Use these to decide the sold/bought amounts to declare.
- 8 Declare settlement** Records the real external currency exchange: it creates two reconciled bank-operations (one sold, one bought) and links them to the internal exchanges in the date range, posting the FX clearing entries. There must be unsettled internal FX exchanges for that pair and range, or it is rejected. The success banner confirms the settlement was declared and linked.
- 9 Internal delta heading** Heading for the left report block. The 'internal delta' is the net effect of investor currency conversions still awaiting external settlement: how much source currency was sold, gross and net target bought, and fees, per currency.
- 10 Realized settlement heading** Heading for the right report block. 'Realized settlement' compares expected vs actual sold/bought amounts from past declared settlements and shows the residual (the small over/under that remains) per currency.

- Load reports is read-only. Declare settlement records money movement; both require an active admin and an enabled pair of different currencies.
- Residuals compare expected internal FX amounts with actual bank execution. Review them by currency in the realized report.
- Choose dates, load reports, reconcile the internal delta against bank evidence, enter actual sold/bought amounts, then declare settlement.

Loans & Marketplace

This screen is the lending engine of BANXUM. It is where you set up the companies that borrow money, build the loans they want, and run those loans from the moment they go live until they are fully repaid or written off.

A quick mental model of the product. Individual investors (called lenders) put money into their BANXUM account. The platform then funds loans to vetted business borrowers. Borrowers repay over time with interest. Lenders earn that interest and can later withdraw.

Borrowers are companies, not people with logins. There is no borrower portal. An admin types in every borrower's details by hand. The borrower never sees this screen.

Two jargon terms you will see everywhere. The primary market is where a brand-new loan is first funded by investors. The secondary market is where an investor who already owns a slice of a loan sells that slice to another investor. This screen handles admin tasks for both.

This page contains key metrics, Loan Originators, Borrowers, Loans, Secondary-market approvals and Servicing operations. Direct-loan actions live in Manage. LO Manage provides publish, close/retry, cancel/refund, hold and replacement-import repayment actions. Holdings activate automatically at funding close; no manual activation action exists.

WHAT YOU DO ON THIS SCREEN

- Add and edit borrower companies. Company KYB is offline; use optional status records and explicit compliance holds for operational visibility. Each borrower form ends with an investor-facing story editor (Medium-style: headings, text, quotes, lists, images, dividers); it is what lenders read on the loan's "Meet the borrower" page, next to the key loan facts.
- Create direct BANXUM loan drafts and review status, amount, yield, LTV and funding deadline. New refinancing-loan creation is disabled; legacy refinancing records remain serviceable.
- Create and maintain Loan Originators after offline KYB, without requiring platform compliance documents. Import claims with selected public borrower disclosure, a finite funding deadline, an LO-owned boundary installment, separate interest/penalty participation, minimum investment and a reconciled CSV. Optional skin in the game is a retained-principal floor; it caps subscription capacity. The Loan Originator form has the same story editor; for claim loans lenders read the originator's story ("Meet the originator"), never the end borrower's private data. Uploaded images are verified as real images, stripped of metadata, resized to at most 1 MB and served only to signed-in users.
- Set each direct loan's minimum subscription (default 50% of the financeable principal) while it is a draft. Publication discloses and permanently freezes the threshold. When the funding deadline passes with the minimum met, the loan is closed and made at the amount subscribed; below the minimum the campaign is cancelled and every reservation is refunded.
- Open Manage on a loan row to publish it to the marketplace, resolve its passed funding deadline from the stored minimum, cancel it when required, release a stuck investor order, disburse a funded loan to the borrower, or record borrower repayments. Published loans cannot be put into effect through a discretionary manual close.
- Approve, reject or remove non-standard secondary-market listings (investor-to-investor resales).
- Service live direct loans through their normal repayment/recovery actions. For originator claims, upload a replacement immutable import revision that preserves every historical payment and adds exactly the newly reconciled borrower payment.

Figure 8.1 The four summary tiles across the top of the Loans screen.

A quick at-a-glance count of borrowers, loans, committed money and loans that need attention. These numbers are derived live from the loaded borrower and loan lists.

- 1

Borrowers Number of borrower companies loaded. Can transact counts companies without an explicit compliance hold or Declined/Manual review decision. Company KYB is completed offline; optional missing or expired platform records do not block transactions.
- 2

Loans The total number of loans loaded, with a sub-count of how many are 'published' (live on the marketplace and open for investors to fund). Watch this to see how much is actively raising money right now.
- 3

Committed The sum of money investors have committed across the loaded loans, shown in minor units (the smallest currency unit, e.g. 100 for 1.00 CHF). This is how much investor money is currently pledged into loans. It is a rough total across mixed currencies in preview data, so treat it as an order-of-magnitude figure.
- 4

Risk items The number of loans whose status is 'late' or 'defaulted'. These are loans where the borrower has missed payments. Watch this closely: a non-zero number means servicing or recovery work is needed.

NOTES & RULES

- These tiles are calculated from the lists below them, not from a separate report. If you filter or refresh the tables, the counts can change.

Figure 8.2 **Loan Originators: accounting entities that sell existing final-borrower claims through BANXUM.**

Create the Loan Originator before importing any of its claim loans. Originators are onboarded and KYB/AML-reviewed off-platform; they do not receive investor-portal login accounts.

- 1

Loan Originators This table is the source of the legal counterparty and settlement configuration used by imported originator-claim loans. Search by public name, legal name or registration number when records exist.
- 2

Refresh Reloads Loan Originators from the backend after a create or update operation.
- 3

Create Loan Originator Opens the originator form. Enter operational identity and settlement details after Garanta completes company KYB offline. Platform evidence references are optional.

NOTES & RULES

- An originator is not a borrower portal user. It owns an existing final-borrower claim and sells eligible portions of that claim through BANXUM.
- Skin in the game is configured per imported claim loan, not globally on this card. A positive basis-point value reserves the required proportion of outstanding principal for the originator and prevents it from being sold.

Figure 8.3 **The Borrowers table: every borrower company and its compliance gate.**

Borrower companies are entered by admins after offline company KYB/AML. No platform compliance file is required. Explicit holds and Declined/Manual review decisions still block transactions.

- 1

Entity column The borrower company's legal name with its unique ID (UUID) underneath. Click anywhere on a row to select that borrower; the selected row is used as the default when you create a new loan.
- 2

Classification column The borrower's business classification (for example 'Residential real-estate development') with a chip showing whether that text is Public or Internal. Public means investors can read it on the loan page; Internal means only admins see it. The choice is made per borrower in the create/edit form.
- 3

KYB column Optional company review status: Not started, Pending, Approved, Declined, Manual review, Expired or Re-verification required. Declined and Manual review block transactions; a compliance hold always blocks. Other values alone do not block, because company KYB is handled offline.
- 4

Country column The borrower's country, or a dash if not recorded. Useful for spotting non-Swiss borrowers at a glance.

- 5

Financials column A short summary of the company's self-reported finances: total assets and last-year revenue, in the borrower's chosen financials currency. This is context only; it does not gate anything automatically.
- 6

Actions column Holds the per-row Edit button. Note there is no delete: borrowers cannot be removed from this screen.
- 7

Filter borrowers by KYB status A dropdown to show only borrowers in a chosen KYB status (or 'All KYB statuses'). Use it to quickly find, for example, every company stuck in Manual review.
- 8

Refresh button Reloads the borrower list from the backend. Use it after creating or editing a borrower if the table has not updated on its own.
- 9

Create borrower button Enter legal name, year founded, entity type, classification, addresses and contact information. Selected-public fields have per-borrower disclosure controls. Ownership, bank accounts, KYB/AML observations and financial risk remain internal. Optional Pending KYB is not a publication block.
- 10

Edit button (row action) Edit operational borrower data, optional company review status and explicit compliance hold. Resolve adverse decisions only after review, with the required audit note or evidence summary.
- 11

Approved chip An optional record of completed company review. Explicit compliance holds still block publishing, disbursement and servicing.
- 12

Manual Review chip An explicit unresolved review decision. Borrower transactions are blocked until Garanta resolves it.
- 13

Public chip This borrower's classification is marked public, so lenders see the same text on the loan's detail page. Only fields explicitly marked public are ever shown to investors; everything else stays internal.
- 14

Internal chip This borrower's classification is internal-only. Investors see nothing for this field. Internal-only borrower data also includes ownership notes, bank-account details, KYB/AML observations and financial-risk notes - none of these ever reach the investor app.

NOTES & RULES

- Garanta completes company KYB offline. Explicit compliance holds and Declined/Manual review decisions block transactions; optional record absence or expiry does not.
- There is no borrower login anywhere in BANXUM. Every field you see here was typed in by an admin.
- The search box (top of the card) lets you find a borrower by legal name, registration number, country or UUID.

Figure 8.4 The unified Loans table: direct loans and Loan Originator claim loans in one operational view.

Each row is one opportunity. Direct loans use borrower funding/disbursement. Current LO claims use an immutable imported schedule, selected public borrower disclosure and a finite at-par subscription. Funding close automatically creates holdings; the boundary installment belongs wholly to the LO. Subsequent principal follows ownership and interest/penalty use declared participation.

- 1

Loan / counterpart column Shows the opportunity title, its borrower or Loan Originator counterpart, and its unique reference. Click a row to select it; Manage always stays pinned to that exact opportunity.
- 2

Product column Distinguishes Direct loans from Originator claims. The two products share an investor-opportunity table but have different creation, publication, settlement and servicing actions.
- 3

Status column The current lifecycle or opportunity status. The server uses this status to decide which Manage actions are available; it is not merely a display label.
- 4

Progress column For a direct loan, shows committed versus financeable principal and the funding percentage. For a current originator claim, it shows reserved subscription principal versus sellable capacity while respecting the retention floor.
- 5

Yield column For direct loans this is the contractual investor rate. For current originator claims this is a nominal participating-coupon indicator; review the separate underlying coupon plus interest and penalty participation in Manage. It is not a guaranteed effective IRR. Internally percentages use basis points (100 bps = 1%).

- 6

LTV column Loan-to-Value: current loan principal divided by eligible collateral value. A lower LTV means more collateral margin. A dash means the product has no disclosed LTV.
- 7

Availability date column For both direct and current originator opportunities this is the funding deadline. Originator Manage also shows contractual maturity and the activation-boundary installment date.
- 8

Actions column Direct loans offer Edit and status-aware Manage actions. Originator claims use their own Manage workflow for imported evidence, publication, holds and replacement repayment revisions. Delete is intentionally unavailable for financial evidence.
- 9

Filter loans by status Narrows the unified table by lifecycle status. Use the search field above it to find a title, borrower, originator, product, status or UUID.
- 10

Refresh button Reloads both product types from the backend after a mutation.
- 11

Create direct loan Creates a draft for a BANXUM-originated direct borrower loan. Select the borrower, principal, yield, term, repayment type, collateral, start date and funding deadline; the server generates and validates the schedule.
- 12

Import originator claim loan Imports a Loan Originator-owned claim from a fully reconciled schedule/payment CSV. The form captures funding deadline, activation-boundary date and expected post-payment principal, separate investor interest/penalty participation, minimum investment and optional skin-in-the-game basis points. A positive retention value is rounded up to a minor unit and remains unavailable to investors.
- 13

Manage button (row action) Opens the product-specific workflow for the selected row. Direct and originator-claim actions are deliberately separated so imported claim evidence cannot be edited through the direct-loan lifecycle.
- 14

Published status chip Example of a direct loan live in the primary marketplace and accepting investor orders.
- 15

Late status chip Example of a 'Late' chip: at least one installment is 5 or more days past due. If it reaches 16 or more days past due, the status scan moves it to Defaulted. Late loans still accept repayments.
- 16

Defaulted status chip A defaulted direct loan is handled through recovery. Every payment still follows the same server-owned order: Garanta legal costs and recovery fee, penalty, interest, then principal.

NOTES & RULES

- Publishing checks required fields, schedule conservation and a deadline within 50 inclusive subscription dates. Company KYB is offline; explicit borrower holds/adverse reviews and originator inactive/hold states still block. LO checks also cover sellable principal, the original boundary row and declared post-boundary principal.
- Current LO orders reserve money in escrow. Full subscription auto-closes; deadline resolution closes any positive round or cancels an empty one. Successful close creates active holdings, fixed post-boundary entitlements and LO payable atomically. A failure preserves reservations, hides the offer and alerts operations. Record the boundary receipt separately as wholly LO-payable.
- If originator close processing fails, funds remain reserved, the opportunity is hidden, and an urgent task plus operations email require repair. The system retries automatically; admins cannot cancel a subscribed expired or failed round instead. Routine KYB expiry does not block close, but an explicit adverse status or hold does. Future resolution dates are rejected; staging time travel uses the QA clock.
- The universal payment waterfall applies to every product and status: Garanta legal costs and recovery fee, penalty, interest, then principal. Principal is never paid ahead of a due earlier tier.
- For an originator claim, imported payment-category columns are reconciliation evidence only. The server recomputes the applied split and rejects a CSV that relabels interest or penalty as principal.
- Status is enforced. Invalid product/status operations are rejected even if a client tries to call the endpoint directly.

Figure 8.5 The Manage dialog: pick the action to apply to this loan.

Clicking Manage on a loan row opens this dialog. The bar at the top restates the loan you are acting on: its status chip, funding deadline, committed versus total amount, and ID. Below it is the action menu - only actions valid for the current status are listed. Draft loans offer Publish; published loans offer Cancel funding, Resolve funding deadline, and Release an order's balance; a funding-close failure offers the same actions so operations can retry or refund; funded loans offer Borrower disbursement; active/late loans offer Record borrower repayment; defaulted loans offer Record a recovery payment.

- 1 Dialog title** Names the loan you are managing, so you cannot mix up rows. Everything you do in this dialog applies to this loan only.
- 2 Loan context bar** The highlighted status sits inside the loan context bar, alongside the funding deadline and committed/total amounts. Check the whole bar before acting - the menu is built from this status.
- 3 Cancel funding** Stops the campaign before close. Reserved balances are released back to investors, pending orders close as not invested, and the loan moves to cancelled. Only valid before funding close. The 'Confirmation required' tag means a summary dialog asks you to confirm before anything runs.
- 4 Resolve funding deadline** After the deadline, compares committed principal with the stored minimum subscription under the same loan lock. At or above the minimum it closes at the subscribed amount; below it, it cancels and refunds. There is no discretionary admin partial-close choice. A processing failure removes the loan from public view, preserves reservations and opens an urgent task.
- 5 Release an order's balance** Returns one allocated order's reserved balance to its investor without touching the rest of the campaign - used when a single order must be unwound, for example after a validation problem.
- 6 Close (X)** Closes the dialog without doing anything. Nothing runs until you pick an action and confirm it inside the form.

NOTES & RULES

- The menu is status-aware: a draft loan offers Publish; a published or funding-close-failed loan offers Cancel/Resolve deadline/Release; a funded loan offers Borrower disbursement; an active or late loan offers Record borrower repayment; a Defaulted loan offers Record a recovery payment. The Servicing operations panel below keeps only the status scan and public risk notes.
- Dangerous actions carry a 'Confirmation required' tag: after filling the form you still get a summary dialog restating loan, reason and message before the backend is called. Repayments in advance additionally show a preview of the allocation and the old and new schedules.
- Publishing is subject to backend gates: no explicit borrower hold or Declined/Manual review decision; company KYB is offline, complete loan data, a valid funding deadline, schedule principal equal to the financeable principal, and for refinancing loans a financeable principal not above the remaining outstanding of the original schedule.

Figure 8.6 Resolve a passed funding deadline from the stored minimum subscription.

The context bar stays visible while the deterministic resolver asks only for an as-of date and scope. The server decides close versus cancellation from the stored minimum under a loan lock. Optional reason/message overrides apply to the below-minimum cancellation path; they cannot change the threshold result.

Resolve funding deadline

2

Funding resolution as-of date

05.08.2026

3

☒ Scan this loan only

When enabled, only this loan is resolved. Disable to process every expired published campaign. Failed campaigns are retried only when selected explicitly.

Below-minimum cancellation reason

Optional. Used only if the campaign is below its minimum and must be cancelled.

Below-minimum investor message

Optional. Sent only if the campaign is below its minimum and investor reservations are refunded.

Resolve funding deadline

4

- 1

All actions (back) Returns to the action menu without running anything. Use it if you picked the wrong action.
- 2

Funding resolution as-of date The Europe/Zurich business date used to decide whether the deadline has passed. Do not future-date it in normal operations.
- 3

Scan this loan only Leave enabled for a targeted retry. Disable only when intentionally resolving every expired published campaign. Failed campaigns are never swept into a broad scan; select them explicitly after fixing the cause.
- 4

Resolve funding deadline button Opens a confirmation summary, then closes at the subscribed amount when the threshold is met or cancels/refunds below it. If processing fails, investor reservations remain unchanged and an urgent operations case is opened.

NOTES & RULES

- The exact minimum is rounded up to a whole minor unit. The decision and close/cancellation run under the same loan lock, preventing an allocation from racing the threshold check.
- Success, preview-mode and error messages appear at the bottom of the dialog, and the loan table refreshes automatically after a successful action.
- In preview/demo mode the buttons record a 'Preview action' note instead of calling the backend.

Figure 8.7 Secondary-market approvals: the table of investor-to-investor resale listings.

Every secondary-market listing, newest first. The secondary market is where an investor who already owns a slice of a loan sells it to another investor. Standard (performing-loan) listings publish automatically and appear here as 'Active'; non-standard listings (late, defaulted, or otherwise flagged) wait as 'Approval requested' until an admin approves them with a buyer disclosure note. The status filter narrows the table, and the action buttons on each row open a confirmation dialog.

Secondary-market approvals

Every secondary-market listing, newest first. Non-standard listings wait here as 'Approval requested' until an admin approves them with a buyer disclosure note.

Zug Park II bridge facility sm-listing-684	Jonas Keller jonas.keller@example.ch	CHF 19'600.00 -2% discount	Active	-	Sold	24 Jun 2026	No actions				

- 1 **Loan / listing column** The loan the listed slice belongs to, with the listing's own ID underneath.

2 **Seller column** The investor selling the slice (name and email). Buyers never see this - seller identity is redacted on the buyer-facing side - but admins need it here to review the listing.

3 **Price column** The transfer price and whether it is a discount or premium to the current principal. Accrued interest and fees are added at settlement.

4 **Loan status column** The underlying loan's status (Published, Late, Defaulted...). This is what makes a listing 'standard' or 'non-standard': a late or defaulted loan needs your approval and a disclosure note before buyers can see it.

5 **DPD column** Days past due on the underlying loan. A non-zero value is a signal to review carefully and disclose the risk to buyers.

6 **Status column** The listing's own status: Approval requested (waiting for you), Active (visible to buyers), Sold, Rejected, Removed, or Cancelled.

7 **Status filter** Narrows the table to one listing status - for example show only 'Approval requested' to work through the queue of listings needing a decision.

8 **Approve (row action)** On an 'Approval requested' row, opens a dialog to approve the listing. You provide a reason and a buyer disclosure note (shown to buyers as the public disclosure), then confirm. The listing becomes Active and visible to eligible buyers with an extra risk acknowledgement.

9 **Reject (row action)** On an 'Approval requested' row, opens a dialog to reject the listing with a reason. It stays hidden from buyers and the decision is audit-logged.

10 **Remove (row action)** On an 'Active' row, opens a dialog to take a live listing out of buyer visibility with an operational reason - used when a listing must be pulled after it went live.

11 **Approval requested chip** This listing is non-standard and waiting for your decision. Only rows in this state show Approve/Reject.

12 **Active chip** This listing is live and visible to buyers. Active rows show a Remove action; sold, rejected and removed rows show no actions.

NOTES & RULES

- Standard (performing-loan) listings publish automatically and never need approval; they appear here as Active so you can still Remove one if needed.
- Approving a non-standard listing requires a buyer disclosure note - the public text buyers must read and additionally acknowledge before purchase.
- Approve, reject and remove are all confirmed in a dialog and recorded in the audit trail with your reason.
- Rejected, removed, sold and cancelled listings stay in the table for evidence but offer no further actions.

Figure 8.8 Servicing operations: scan loan health and post public notes.

Servicing means running a loan after it is funded. This panel now holds only the status scan and public investor notes for the loan selected in the table above. Borrower repayments (a fixed regular installment amount, or 'Repayment in advance' with a bank date and a preview dialog) and recovery payments on defaulted loans are recorded from the loan row's Manage dialog.

Servicing operations

SELECTED LOAN **Zug Park II bridge facility** loan-zug-park-ii

1

Loan

loan-zug-park-ii

Selected ID: loan-zug-park-ii

2

Run status scan

3

Risk note body

Public servicing update for affected investors.

4

Publish public note

Borrower repayments are declared from the loan row: use **Manage → Record borrower repayment**. Recording a recovery payment for a defaulted loan is done via **Manage → Record a recovery payment**.

- 1

Loan field The loan being scanned or noted. It defaults to the selected loan but can be changed by search.
- 2

Run status scan button Re-checks the loan's health and updates its status. A loan with an installment 5+ days past due becomes Late; 16+ days past due becomes Defaulted; fully paid becomes Repaid. The scan is the only thing that escalates a loan into Defaulted; recording a repayment never does.
- 3

Risk note body field The text of a public update to investors about this loan (for example explaining a delay). This is the message that gets published when you press Publish public note.
- 4

Publish public note button Posts a public risk note that investors holding this loan can read. Public notes are only allowed on loans that are in an active portfolio status (Funded, Late, Defaulted, Repaid or Written off), not on drafts or unfunded loans.

NOTES & RULES

- Borrower repayments are recorded from Manage > 'Record borrower repayment': a regular installment uses the fixed outstanding amount of the next due installment (not editable), and any other amount uses 'Repayment in advance' with a 'Borrower repayment bank date' plus a mandatory preview of the allocation and the old and new schedules. The old warning-acknowledged checkbox for partial/irregular amounts was removed.
- Each action uses an idempotency key, so an accidental double-submit is safely ignored rather than processed twice.
- Recovery payments on a defaulted loan are recorded from the loan row's Manage dialog (Record a recovery payment), not here.

Figure 8.9 Manage > Record a recovery payment (defaulted loans only).

The recovery action appears in the Manage dialog only when the loan is Defaulted. Record the gross cash, evidenced costs, optional Garanta recovery fee, and amounts currently due for penalties/default interest and contractual interest. The server derives current principal and applies one fixed order: costs/recovery fee, penalty, interest, then principal. The operator cannot choose or reorder the applied split.

FUNDING DEADLINE 28 FEB 2026

COMMITTED CHF 350'000.00 / FINANCEABLE CHF 350'000.00

loan-luzern-quartier

← All actions

Record a recovery payment

Record funds recovered on this defaulted loan. The recovered amount, minus external and third-party costs and the optional Garanta recovery fee, is allocated by the server in one non-overridable order: penalty, contractual interest, then principal.

2

Gross recovered

1000000

Formatted amount: CHF 10'000.00

3

Externally deducted costs

0

Formatted amount: CHF 0.00

4

Third-party costs (from received)

0

Formatted amount: CHF 0.00

5

☐ Apply Garanta recovery fee

Applies the configured Garanta recovery fee on the net-of-third-party base.

NET RECEIVED CHF 10'000.00

FEE CHF 0.00

NET TO DISTRIBUTE CHF 10'000.00

6

Outstanding default/penalty interest

0

Formatted amount: CHF 0.00

7

Outstanding other penalties

0

Formatted amount: CHF 0.00

8

Outstanding contractual interest

0

Formatted amount: CHF 0.00

1. COSTS AND RECOVERY FEE CHF 0.00

2. PENALTY CHF 0.00

3. INTEREST CHF 0.00

4. PRINCIPAL CHF 10'000.00

Enter evidence-backed amounts currently due. Principal is derived from active holdings and receives only the remainder after every higher tier is satisfied. The backend rejects any recovery larger than the total outstanding obligations.

Booking date

05.08.2026

Value date

Record recovery

9

1

Defaulted status The recovery action only exists for a Defaulted loan. On any other status the Manage menu does not offer it (repayments on funded or late loans are recorded through Manage > 'Record borrower repayment' instead).

2

Gross recovered The total amount recovered on the loan before any deductions - for example proceeds from enforcing collateral.

3

Externally deducted costs Costs already taken out before the money reached Garanta (deducted from the gross). Net received = gross minus these.

4

Third-party costs (from received) External legal or recovery costs paid out of the received funds. These come off before the Garanta fee and the lender distribution.

5

Apply Garanta recovery fee Tick to apply Garanta's recovery fee. A basis-points field appears; the fee is charged on the net-of-third-party base and becomes Garanta revenue.

6

Outstanding default/penalty interest Enter the evidence-backed default or penalty interest currently due. It belongs to the Penalty tier and is paid before contractual interest or principal.

- 7

Outstanding other penalties Enter any other evidenced penalties currently due. Together with default/penalty interest, this is the second waterfall tier.
- 8

Outstanding contractual interest Enter contractual interest accrued and still due. The server pays it only after costs/recovery fee and the complete penalty tier.

- 9

Record recovery Opens the confirmation summary, then records the recovery. Affected investor balance lots are credited, holding principal is reduced only by the amount that reaches the final tier, and Garanta recovery fee is posted as revenue.

NOTES & RULES

- Recovery is only valid on a Defaulted loan; repayments on funded/late loans go through Manage > 'Record borrower repayment' (fixed installment amount, or 'Repayment in advance' with a bank date for any other amount).
- The Net received / Fee / Net to distribute summary mirrors the gross-to-net calculation. A second summary previews the fixed four-tier allocation; there is no editable principal-first split.
- Principal is never paid while evidenced costs/recovery fee, penalties/default interest, or contractual interest remain due.
- In preview/demo mode the button records a 'Preview action' note instead of calling the backend.

Reports & Audit

This screen has two jobs. On the left you generate exports: data files that pull together accounting, tax, regulatory, and day-to-day operational records into a single download. On the right you search the audit log: a permanent record of who did what, to what, and when.

A "report" here is just a structured snapshot of platform data for a chosen date range, produced as a file you can hand to accountants, auditors, regulators, or banks. You pick what data you want (the report type), the file format (CSV, PDF, or ZIP), how much sensitive detail to include (the redaction mode), and the time period. The system builds the file on demand and gives it back to you to download.

The audit log is the platform's tamper-proof history book. Every meaningful action by staff or the system is written here once and can never be edited or deleted (it is "append-only"). It records the actor (who), the action (what they did), the target (what it was done to), and the exact time. It is your evidence trail when someone asks "who changed this?".

Important context for a newcomer: PII means "personally identifiable information" such as names and account-owner IDs. Some reports and the "Full" redaction mode expose this sensitive data, so the system restricts them to senior staff (superadmins). Generating any report itself writes an entry into the audit log, so report generation is never invisible.

WHAT YOU DO ON THIS SCREEN

- Generate an accounting, tax, regulatory, or operational export by choosing a report type, output format, redaction mode, and date range, then clicking Generate report.
- Choose how much sensitive detail the export contains using the redaction mode (Redacted hides personal identifiers; Full shows everything and is superadmin-only).
- Set the reporting period either with a quick preset (daily, weekly, monthly, quarterly, yearly, calendar year) or with custom start and end dates.
- Download the finished file, and verify its integrity using the SHA-256 checksum the system records for each run.
- Search and review the immutable audit log to see who performed which action against which target, and exactly when it happened.

Figure 9.1 The Report generation form: choose what to export, in what format, how redacted, and for which period.

A form that builds a data export on demand. You select the report type, output format, redaction mode, and period, then click Generate report; the system returns a downloadable file plus a checksum and manifest.

Generate report

- 1

Report generation (panel title) Marks the left-hand panel where you build exports. It generates accounting, tax, regulatory, and operational files on demand for a chosen date range.
- 2

Report type (field) Picks which dataset to export. This is the single most important choice: it decides what rows appear in the file.

- 3 **Report type dropdown** The list of available exports. The options are: Operational subledger, Trial balance, Garanta accrued revenue, Bexio accounting export, Bank operations, Reconciliation, Investor balances, Balance ageing, Withdrawals, Loan funding, Repayment status, Default exposure, Recovery/write-off, FX activity, KYC status, Audit log, Failed outbox, Participant account statement, and Annual tax information. Gotcha: four of these contain restricted data and can only be generated by a superadmin: KYC status, Audit log, Participant account statement, and Annual tax information. A regular admin who selects one of these gets a permission error ("requires an active superadmin").
- 4 **Output format (field)** Chooses the file type the export is delivered as. It does not change which data is included, only how the file is packaged.
- 5 **Output format dropdown** Three choices: CSV (a plain spreadsheet-style text file, best for accountants and re-import), PDF (a formatted, print-ready document), and ZIP (an evidence package that bundles the data and a manifest). CSV comes back as plain text; PDF and ZIP come back base64-encoded, which means you cannot read them in the on-screen preview and must click Download artifact to save the actual file.
- 6 **Redaction mode (field)** Controls how much personally identifiable information (PII) the export reveals. This is a privacy and compliance control, so treat it carefully.
- 7 **Redaction mode dropdown** Two choices. Redacted (the default and safe option): personal identifiers such as account-owner IDs, lender user IDs, bank references, and evidence references are replaced with the literal word REDACTED. Full: every identifier and detail is shown in the clear. Hard rule: Full mode is superadmin-only. If a regular admin selects Full, the system refuses with "Full report exports require an active superadmin." Use Redacted unless you have a specific, authorized reason for Full.
- 8 **Period preset (field)** Lets you pick a standard reporting window quickly instead of typing two dates.
- 9 **Period preset dropdown** Choices: Custom, Daily, Weekly, Monthly, Quarterly, Yearly, and Calendar year. With Custom, you must fill in both Start date and End date below. With any other preset, the system ignores the start date and uses the End / anchor date as the anchor point, then expands it automatically: Daily = that single day; Weekly = the Monday-to-Sunday week containing it; Monthly = the whole calendar month; Quarterly = the whole quarter; Yearly and Calendar year = the whole calendar year (Jan 1 to Dec 31).
- 10 **Start date (field)** The first day included in the export. It is only used when Period preset is set to Custom. With any other preset this field is ignored. Rule: in Custom mode the end date must be on or after the start date, or the request is rejected.
- 11 **End / anchor date (field)** Does double duty. In Custom mode it is the last day included. With any other preset it is the "anchor" date the system builds the window around (for example, in Monthly mode the system takes the month that contains this date). It is required for the preset modes.
- 12 **Destination note (field)** A free-text note describing why or for whom the report was produced (for example "Q2 auditor request"). It is stored on the report run record and the audit log records whether a note was present, so use it to leave a paper trail. It does not change the report's contents.
- 13 **Generate report (button)** Builds the export now. On success the system creates a permanent report-run record, writes an audit-log entry (action reporting.report_generated), and returns the file plus its details. The result panel that appears below shows the filename, the row count, a SHA-256 checksum you can use to prove the file was not altered, the generation timestamp, the encoding, a content preview (CSV only), and a manifest. A Download artifact button there saves the actual file. Gotcha: in preview mode no real file is produced; only a placeholder message appears.

NOTES & RULES

- Permission gates enforced by the backend: only an active admin can generate any report; Full redaction mode is superadmin-only; and the four restricted types (KYC status, Audit log, Participant account statement, Annual tax information) are superadmin-only regardless of redaction mode.
- Every generated report is itself recorded: it creates an immutable report-run row, a report event, and an audit-log entry. There is no way to generate a report silently.
- Each report run carries a SHA-256 checksum and a fixed definition version (reporting-v3). The checksum lets a recipient confirm the file they received is byte-for-byte the one that was generated.
- Repayment status includes direct loans and Loan Originator claims, identified by product, loan and originator. LO rows distinguish imported payments from the remaining schedule and show actual investor credits, LO payable and Garanta costs where recorded. Blank distribution fields mean no platform payment evidence, not zero payment.
- Repayment reports select the schedule version known at the period end and exclude superseded unpaid rows and later-value-date repayments. Historical payment rows remain visible, including a full early payoff with an empty replacement schedule. Balance ageing and investor balances reconstruct amounts from dated financial evidence rather than today's mutable lot balances. Later backdated corrections can restate a newly generated export; keep the original artifact and checksum when comparing periods.
- The generated filename follows the pattern reporttype_startdate_enddate.extension (for example operational_subledger_2026-01-01_2026-03-31.csv).
- PDF and ZIP outputs are base64-encoded and cannot be read in the on-screen preview; you must download them. Only CSV shows a readable preview (first 2000 characters).

Figure 9.2 The Audit event search panel: a read-only, time-ordered table of recent platform actions.

A table of the most recent audit-log entries (newest first). Each row is one recorded action and shows when it happened, what it was, who did it, and what it was done to. The log is append-only evidence: entries can never be edited or removed.

- 1

Audit event search (panel title) Marks the right-hand panel that lists recent platform actions for operational review. It is a read-only view onto the immutable audit log, not a place to change anything.
- 2

Refresh (button) Reloads the latest audit entries from the backend. Use it after performing actions elsewhere to pull in newly recorded events. It only re-reads data; it cannot alter the log.
- 3

When (column) The exact date and time the action was recorded (the occurred_at timestamp). Rows are shown newest first. This timestamp is set automatically when the event is written and cannot be changed afterwards.
- 4

Action (column) What happened, as a machine-readable code (for example reporting.report_generated). The prefix before the dot tells you the area of the platform; the part after describes the act. This is how you find all events of a given kind.
- 5

Actor (column) Who performed the action, shown as actor_type:actor_id (for example admin:<id>). The actor can be a staff member or an automated system process. This answers "who did it?"
- 6

Target (column) What the action was performed on, shown as target_type:target_id (for example report_run:<id>). Together with Action and Actor it forms the full sentence: this actor did this action to this target at this time.

NOTES & RULES

- The audit log is append-only: entries are written once and the system actively blocks any attempt to update or delete them. This is what makes it trustworthy evidence in a dispute or audit.
- This panel loads the most recent entries (up to 100) and shows them newest-first. It is a review view; there are no editable filter inputs on this figure, so use Refresh to pull the latest events.
- Beyond the four visible columns, each event also stores a request ID and a free-form metadata object behind the scenes, which give extra context for investigations.
- If no events are returned the panel shows an empty state reminding you that richer filtering becomes available once the production audit-log endpoint is fully live.
- Note the distinction: the Audit log report type on the left exports the audit log as a file (and is superadmin-only), while this panel is for quick on-screen review.

Superadmin Settings

This screen is the governance area of the admin console. It is locked to superadmins. A superadmin is the highest level of staff account; a plain admin cannot open most of what is here.

There are two kinds of accounts on BANXUM. Investors (also called lenders) are the public users who deposit money and fund loans. Admins are Garanta staff who run the platform from this console. They are completely separate; an investor is never an admin.

Use this area to manage legal document templates and platform-wide settings. User lookup, access changes and admin creation are in Users. On staging/local, the separate QA mode section lets active regular admins as well as superadmins fast-forward time, save a checkpoint and restore either that snapshot or the original seed. QA controls never appear on production.

A note on jargon. 'Clickwrap' means the small legal text plus tick-boxes a user agrees to before an action (like accepting terms). A 'template' is the wording of that text. A 'version' is one dated snapshot of that wording. 'Immutable' means once saved it can never be edited; you only ever create a new version. This matters because every acceptance is kept as legal evidence tied to the exact version the user saw.

WHAT YOU DO ON THIS SCREEN

- Browse the versioned legal/document templates for each category, and see which version is currently live (the 'Current' one).
- Create a new draft version of a template, or publish a version so it becomes the live one shown to investors.
- Confirm that the current Registration template and Primary Market Investment template are published before live onboarding or investment testing. The primary-market template produces one project investment confirmation PDF per investment order.
- Create a new admin staff account (only an active superadmin is allowed to do this).
- Search the full user directory (admins and investors) by name, email, investor reference, or UUID.
- Open the separate QA mode section on staging/local to advance time, create a snapshot, Restore snapshot or Restore seed. Active regular admins can also do this. Restoring the seed keeps its original QA date; the independent saved checkpoint does not replace it. Restores validate the checksum and schema and run atomically under an exclusive lock. The restoring admin normally remains signed in with a fresh session; other sessions sign in again. The environment owner must upgrade saved baselines after schema changes. Production rejects all QA actions.
- Account-level actions (create admin staff, restrict/lock/close accounts, read-only investor views) moved to the Users module; this screen keeps a pointer card so you know where they went.

Figure 10.1 Document templates: versioned legal text by category, with create-version and publish actions.

This card lists the legal/clickwrap templates investors must accept. Each row is one version of a template. Versions are immutable: you never edit one, you create a new version and then publish it to make it live. The list is filtered by the Category dropdown at the top. The Primary Market Investment category is the project investment confirmation / claim assignment agreement that is generated for each investor order.

- 1 **Category filter (label)** This label marks the Category picker. A category is the situation where a document is shown to a user. The table only shows templates for the category you pick here.

2 **Category dropdown** Pick which kind of document to view. The four choices are Registration (the lender user agreement accepted when signing up), Primary Market Investment (the project investment confirmation and claim assignment agreement accepted once per primary investment order), Secondary Market Purchase (accepted when buying an existing loan piece from another investor), and Secondary Market Listing (accepted when putting a loan piece up for sale). Changing this reloads the list below.

3 **Refresh button** Reloads the template list from the backend. Use it after someone else has created or published a version so you see the latest state.
- 4 **Create version button** Opens a form to write a brand-new version of a template: name, title, body text, and the tick-box labels the user must accept. You can optionally tick 'Publish immediately'. A new version is always created fresh; it never overwrites an old one. Only a superadmin can do this.

5 **Template column** The template's name plus its unique ID (UUID). Each row under here is one saved version of that template's wording.

6 **Status column** Shows whether a version is a Draft (written but not yet live) or Published. The row that is the live one for its category shows a green 'Current' chip instead.

7 **Current status chip** A green 'Current' chip marks the one version that investors actually see right now for this category. Only one version per template can be Current at a time. Other published versions stay on record as history.

- 8

Version column The version number (v1, v2, and so on). Numbers only ever go up. A higher number is a newer snapshot of the wording.
- 9

Published column The date and time this version went live. Blank means it is still a draft and has never been published.
- 10

Hash column The content hash: a long fingerprint code calculated from the exact text and tick-box labels. It proves the wording has not changed. Two versions with the same hash contain identical content.
- 11

Actions column Per-row actions. Holds the 'Publish / clone' button for that version.
- 12

Publish / clone button Makes the selected version the live 'Current' one. Gotcha: if the version is still a draft, publishing does not change it in place. The system creates a new published copy (a clone) of that text with the next version number and a recorded legal-review reference, and points 'Current' at the clone. The draft you started from stays as it was. Any version already accepted by investors is always preserved.

NOTES & RULES

- In preview mode the screen uses dummy templates. On the live system, every create and publish writes a permanent, immutable document version that cannot be altered afterward.
- When publishing, you can record a 'Legal review reference' (a pointer to the legal sign-off for that wording). This is captured so there is an audit trail of who approved the text.
- Production legal templates should normally be imported from the counsel-approved DOCX sources by an engineer using the import commands, then reviewed here. The current commands are import_lender_user_agreement for Registration and import_project_investment_confirmation for Primary Market Investment.
- The project investment confirmation PDF fills order, loan, borrower, lender, assignment and operator fields from server data at acceptance time. Do not type real investor/loan IDs into the template body; use the approved variables. The final holding ID is assigned at funding close, so the v1 template shows that field as assigned at funding close unless a later post-close assignment artifact is implemented.
- Every accepted document can be regenerated as PDF/CSV from immutable evidence and is also emailed as a PDF package when the email dispatcher processes the acceptance outbox message.
- There is no way to delete a template version from this screen, and the small note next to the action confirms removal is not supported. Document evidence must be kept.

Figure 10.2 User account administration moved to the Users module.

This card is only a signpost. Earlier console versions managed admin staff and account access from this screen; those tools now live in the Users module (Section 5) so every account-level action is reviewed in one place. Nothing is configured on this card.

1

User account administration

Admin users and user account access controls now live in the Users module so account-level actions are reviewed from one place.
Open the Users module to search platform users, create admin accounts, restrict or reactivate accounts, and start superadmin read-only views.

- 1

User account administration heading A pointer card, not a tool. Open the Users module from the left rail to search platform users, create admin accounts, restrict or reactivate accounts, review accepted documents, and start superadmin read-only views.

End-to-end workflows

Step-by-step recipes that connect the screens for the jobs you will actually do. Each step names the screen and the control to use.

1 Onboard a borrower and publish their first loan

Goal: Take a brand-new business borrower from nothing to a live, investable loan on the marketplace. · **Who:** Operations admin (any active admin can do every step).

Before you start:

- You are signed in to the ops console (email + password, then a 6-digit code sent to your admin email).
- A borrower is a business without a portal login. KYB means Know Your Business: Garanta completes and retains company checks offline. Platform KYB records are optional; explicit compliance holds and Declined or Manual review decisions block transactions. A draft is not public; publishing opens it to investor funding.
- You have the borrower's legal details (legal name, year founded, country) and the loan terms (amount, rate, term, collateral).
- A current Primary Market Investment document template is published in Superadmin Settings. Without it, investors cannot complete the investment clickwrap because the server cannot load the project investment confirmation / claim assignment agreement.

1

Loans (left nav 'Loans')

Open the Loans module and go to the 'Borrowers' card.

The Borrowers table lists every business entity. Borrowers are admin-entered only; borrowers do NOT have their own login. If the company is not in the list, you must create it.

2

Loans > Borrowers

Click 'Create borrower' (top-right of the Borrowers card).

A modal opens. Fill Legal name, Year founded, Entity type, KYB status, Country, Financials currency, Assets. New borrowers normally start with KYB status 'Pending'. Click 'Create borrower' to save.

3

Loans > Borrowers

Confirm company KYB/AML is complete offline. Use Edit if you need to update optional status or resolve an explicit restriction.

A local Approved status is not required. Explicit compliance holds and Declined/Manual review decisions still block publishing and transactions. Changing an optional KYB status requires an Admin note or Evidence summary; do not clear an adverse decision merely to publish.

4

Loans > Loans card

With the borrower selected, click Create loan and confirm the borrower in the form.

Enter title, financeable principal in minor units, currency, interest bps, term, purpose, repayment type, collateral/value, risk rating, start date, funding deadline, investor summary and minimum subscription (default 5000 bps = 50%). Publication freezes financeable principal and minimum subscription; the deadline resolver applies that threshold automatically. The first installment is one month after the start date. New refinancing products are disabled: use Create originator claim for an existing LO-owned loan.

5

Loans > Loans card

Confirm the new loan appears with status 'Draft'.

Draft validation checks principal limits, a 1-600 month term, a non-past funding deadline within 50 inclusive subscription dates, and a complete schedule whose principal sums to the financeable amount. Publication imposes the same 50-day inclusive limit.

6

Loans > Manage (loan row)

Click Manage on the draft, choose Publish loan, review the readonly schedule, then click Publish loan after schedule review.

The borrower must have no explicit hold or Declined/Manual review decision. Required loan data and the schedule must reconcile, and the funding deadline must be today or at most 49 days away (50 inclusive subscription dates). Publishing freezes financeable principal and minimum subscription. Legacy refinancing drafts retain their two-step original/new schedule review and original-outstanding checks; new refinancing creation is disabled.

Result: The loan is 'Published' and visible to investors on the primary marketplace; investors can now pledge funds to it.

Watch out for

- If a borrower gate blocks publishing, investigate any explicit compliance hold or Declined/Manual review status. Optional KYB absence, Pending or Expired alone is not a blocker.
- If publish fails on the funding deadline, the deadline is more than 49 days away (over 50 inclusive dates) (or already passed). Edit the loan and set a deadline within 50 inclusive subscription dates.
- Borrowers cannot be deleted - only edited. A 'No delete' note marks this; records are kept for audit.

2 Match an incoming bank deposit to a lender

Goal: When money lands in the Garanta collection bank account, credit it to the correct investor's BANXUM balance. · **Who:** Operations admin (finance).

Before you start:

- Jargon: 'lender' / 'investor' = an individual who puts money on the platform to fund loans. 'Deposit' = an incoming bank transfer from that investor. The 60-day holding clock for the resulting balance lot run from the deposit's VALUE DATE (the value_date field you enter), not the day it arrived or the day

you keyed it - so entering the value date correctly matters, it sets when reminders fire and when the lot becomes over-age. 'Minor units' = the smallest currency unit; CHF and EUR have 2 decimals, so 2500000 minor units = 25,000.00. 'BX-currency-reference' / investor reference = the code the investor was told to put in the payment reference; it starts with 'L' followed by 8-9 characters (e.g. LXXXXXXXXX). 'Collection account' = Garanta's own bank account that received the money. Launch accounts are Garanta_CHF (IBAN CH1183019GARANTAFI001, QR IBAN CH8330334GARANTAFI001, BIC YAPECHZ2) and Garanta_EUR (IBAN CH8183019GARANTAFI002, BIC YAPECHZ2).

- You have the bank statement line: amount, currency, dates, payer name, source IBAN, and payment reference. The source IBAN must be copied from the statement; a guessed or checksum-invalid account is rejected.

- 1

Finance ops (left nav 'Finance ops')

Open Finance ops and go to the 'Lender deposit' card.
This is the first card in the finance grid.
- 2

Finance ops > Lender deposit

In 'Payment reference', paste the bank-statement reference first.
If the reference contains a valid investor reference (the L-code), the 'Investor from bank reference' search box auto-fills with that code so the right investor surfaces immediately. This is the fastest, most reliable match.
- 3

Finance ops > Lender deposit

If there is no usable reference, type the payer's name (or email) in the 'Payer name' field, or search directly in the 'Investor from bank reference' lookup.
On the Lender deposit card the investor lookup matches on reference, full name, email, and UUID only - it does NOT match on IBAN (IBAN matching is wired only into the Payout instruction card's lookup). You MUST pick a result from the list - typing a name that is not selected will block submission.
- 4

Finance ops > Lender deposit

Enter 'Amount minor units' (the field's exact label), Currency, Booking date, Value date, and confirm the Collection account.
Watch the live 'Formatted amount' helper under the amount box - it shows, e.g., 'CHF 25,000.00' so you can sanity-check you did not slip a decimal. Enter whole minor units only.
- 5

Finance ops > Lender deposit

Copy the payer's Source IBAN from the bank statement, then complete payer name and reference evidence.
Source IBAN is required. The backend removes spaces, uppercases it, checks the country-specific length and MOD-97 checksum, and rejects the entire deposit before ledger mutation if it is invalid.
- 6

Finance ops > Lender deposit

Click 'Declare deposit'.
GATES: currency enabled, positive amount, eligible lender, and valid source IBAN. On success the reconciled bank operation, balanced ledger entry, balance lot, and active verified payout instruction for that exact source IBAN/currency are committed atomically. If the investor paid CHF by QR bill, remember that the QR itself did not carry the investor-specific BANXUM reference; verify the bank reference still contains the displayed BX-CHF-... code before matching automatically.

Result: The investor's available balance increases by the deposited amount; the reconciled bank operation and ledger entry are audited; and the valid source IBAN becomes a verified payout destination without a second verification step.

Watch out for

- Do not guess the investor from the payer name alone if a reference exists - names can collide. Prefer the investor reference in the BX-{currency}-{investor_reference} payment reference.
- Entering major units (25000) instead of minor units (2500000) credits 250.00 instead of 25,000.00. Always read the 'Formatted amount' helper.
- Pending-KYC lenders can receive deposits, but restricted, locked, closed, non-lender, or inactive accounts are rejected. If the lookup shows a blocked account, resolve the account status before declaring the deposit.

3

Resolve a KYC case routed to manual review

Goal: Make and record the Garanta decision on an investor identity check that the provider could not auto-clear. · **Who:** Compliance / AML officer (active admin).

Before you start:

- Jargon: 'KYC' = Know Your Customer, the identity check on an individual investor. 'AML' = Anti-Money-Laundering. 'Didit' = the external provider that runs the check. 'Manual review' = Didit could not decide automatically and handed the case to Garanta. 'PEP' = Politically Exposed Person (extra scrutiny). 'Sanctions hit' = the person appears on a sanctions list. 'Reason code' explains why the decision was made.
- You have reviewed the provider's evidence (the provider report ID and AML screening ID are shown on the case row).

- 1

Compliance (left nav 'Compliance')

Open Compliance and read the 'KYC manual review' table.
Each row shows the subject, current status, risk classification, detected flags (e.g. 'Pep Hit', 'Adverse Media Hit'), provider reference IDs, and last update time. The KPI tiles at the top count manual-review cases, PEP/high-risk cases, and cases with no Garanta decision yet.
- 2

Compliance > KYC manual review

Click the case row you want to work. It becomes the selected case and pre-fills the decision form on the right.
Selecting a row copies its case ID into the 'Record AML decision' form's KYC case lookup.

- 3

Compliance > Record AML decision

Choose a 'Decision': Approve, Decline, Request Reverification, or Reopen.
What each does: Approve -> case becomes Approved (and if the investor was pending_kyc, their account is activated). Decline -> Declined. Request Reverification -> sends the person back to redo verification. Reopen -> puts the case back into Manual Review.
- 4

Compliance > Record AML decision

Pick a 'Reason code' (e.g. Pep Review, Sanctions Review, Adverse Media Review) and write an Officer note and/or Evidence summary.
GATE: the backend requires at least one of Officer note or Evidence summary - a blank decision is rejected.
- 5

Compliance > Record AML decision

Click 'Submit KYC decision'.
NON-OVERRIDABLE GATE: you CANNOT manually Approve a case whose current status is 'Sanctions Hit' or 'Declined' - the server refuses it. You can only Approve cases currently in a review-routed status (manual_review, high_risk, pep_hit, adverse_media_hit). A sanctions or confirmed-fraud block must stay blocked. The decision is written immutably to the audit trail.

Result: The case moves to its new status, the investor is activated if approved, and the decision plus reason and note are audit-logged.

Watch out for

- You cannot 'approve away' a sanctions hit or a decline. If the law says no, the system says no.
- Approve only after you have actually read the provider evidence - the screen reminds you of this.
- A PEP or adverse-media flag does not auto-block; it requires your explicit, documented decision.

4

Verify an additional payout IBAN and execute an investor withdrawal

Goal: Review an investor-requested destination account without removing their verified deposit-source IBAN, then finalize or cancel the bank transfer. · **Who:** Operations admin (finance).

Before you start:

- Jargon: 'IBAN' = the international bank account number money is sent to. 'Payout instruction' = the stored, verified IBAN BANXUM is allowed to pay this investor at. 'Withdrawal' = the investor's request to take money off the platform; it sits in status 'requested' until you execute the bank transfer and 'finalize' it. 'Finalize' = confirm the bank actually sent the money and clear the liability in the ledger.
- The investor has a requested withdrawal waiting, OR an automatically created Payout instruction verification task for an additional IBAN. A valid source IBAN from a declared deposit is already verified automatically and does not need this flow.

- 1

Finance ops > Pending finance operations

Open Finance ops and locate the payout-verification task or pending withdrawal at the top of the screen.
The pending table combines unresolved finance tasks with actionable money-operation queues. A self-service IBAN request appears here automatically; use its linked instruction to continue in the Payout instruction card.
- 2

Finance ops > Payout instruction

Select the investor in 'Investor / payout owner', then enter Currency, Destination IBAN, and Account name.
IBAN COLLISION WARNING: as you fill the IBAN, the investor lookup checks how many investors already have a payout instruction with that IBAN. If more than one investor matches, a yellow banner 'IBAN matches multiple investors' appears - stop and confirm you are paying the right person before saving (the same IBAN on two investors usually signals a data error or fraud).
- 3

Finance ops > Payout instruction

Tick 'IBAN is usable and verified for this investor' once you have verified it, then click 'Register payout instruction'.
GATES: the investor must be a lender account, the currency enabled, and the IBAN must pass country-length and MOD-97 checksum validation. This adds or verifies that exact IBAN; it does not disable verified deposit-source accounts. If the investor requested it through Settings, successful verification also resolves the linked finance task.
- 4

Finance ops > Withdrawal execution

Go to the 'Withdrawal execution' card and pick the withdrawal in the 'Requested withdrawal' lookup.
The lookup only shows withdrawals currently in status 'requested'. It searches by lender name, email, reference, withdrawal UUID, or IBAN suffix.
- 5

Finance ops > Withdrawal execution

After you have actually sent the money from the bank, enter Booking date, Value date, Collection account, and an Admin note, then click 'Finalize withdrawal'.
GATE: only a withdrawal still in 'requested' can be finalized; re-finalizing an already-finalized one just returns the existing result. Finalize records the outgoing bank operation and clears the withdrawal-payable in the ledger.
- 6

Finance ops > Withdrawal execution

If the transfer should NOT go out, click 'Cancel before execution' instead of finalizing.
GATE: cancel only works while the withdrawal is still 'requested' (before any bank execution). Cancelling restores the investor's balance lots and reverses the reservation. Provide a cancel reason in the 'Admin note / cancel reason' box.

Result: The destination IBAN is on file as verified; the withdrawal is either finalized (money paid, ledger cleared) or cancelled (funds returned to the investor's balance).

Watch out for

- Never tick 'verified' until you have genuinely confirmed the IBAN belongs to that investor - verification is what unlocks automated forced payouts.
- Finalize ONLY after the bank transfer has actually been made; finalizing is the record that the money left.
- If you see the multi-investor IBAN banner, do not save until you have explained it - it can mean two people share an account or a typo.

5 Handle a day-60 forced withdrawal

Goal: Return funds that an investor has held idle past the 60-day regulatory limit, then pay them out. · **Who:** Operations admin (finance).

Before you start:

- Jargon: 'balance lot' = a dated chunk of an investor's money; each lot's ageing is tracked from the deposit's VALUE DATE (the value_date entered on the deposit), not literally the day it arrived. 'Ageing' = how old a lot is. The platform must not hold uninvested money beyond 60 days. 'Forced withdrawal' = the platform automatically returning over-age funds to the investor. 'Penalty mode' = what happens to an over-age lot when there is NO verified payout IBAN to send it to: the lot is moved to penalty mode AND a real per-day penalty (rate BALANCE_PENALTY_BPS_PER_DAY) is charged against the lot's available balance every time the scan runs while it stays overdue. Penalty mode also blocks FX exchanges and secondary-market purchases until resolved; withdrawal remains the intended way out. Reminder days fire at 25, 46, 53, 58, 59, 60 days held.
- Investors with over-age lots need a verified payout instruction on file (see the payout-IBAN flow) for a forced withdrawal to be created automatically.

- 1

Daily dashboard

On the dashboard, open the 'Balance ageing' and 'Forced withdrawals' queues to see what is near or past 60 days.

'Balance ageing' lists lots near or past the 60-day holding windows; 'Forced withdrawals' lists day-60 return-of-funds withdrawals already generated by the ageing scan.
- 2

Finance ops > Balance ageing scan

Open Finance ops, go to 'Balance ageing scan'. First run it as a DRY RUN (leave 'Dry run only' ticked) to preview.

Optionally set 'As of timestamp' and a 'Currency filter'. A dry run reports how many reminders are due and how many forced withdrawals WOULD be created, without changing anything.
- 3

Finance ops > Balance ageing scan

When the preview looks right, untick 'Dry run only' and click 'Run ageing scan' for real.

GATE / BEHAVIOR: for each investor whose lots are past the withdrawal deadline, the scan checks for an active VERIFIED payout instruction. If one exists, it CREATES a forced withdrawal request (status 'requested') for the over-age amount. If NONE exists, the lot instead moves to 'penalty mode' and no withdrawal is created - and on this and every subsequent live scan while still overdue, the scan charges a real daily penalty (rate BALANCE_PENALTY_BPS_PER_DAY) against the lot's balance, recording a journal entry each time. So registering a verified IBAN (see the payout-IBAN flow) and re-running is TIME-SENSITIVE, not just bookkeeping.
- 4

Finance ops > Withdrawal execution

Go to 'Withdrawal execution', pick the newly generated forced withdrawal in the 'Requested withdrawal' lookup, send the bank transfer, then click 'Finalize withdrawal'.

A forced withdrawal is executed exactly like a normal one - it lives in the same 'requested' withdrawal queue. Enter Booking date, Value date, Collection account, and finalize after the money has been sent.

Result: Over-age funds leave the platform as finalized withdrawals; lots with no verified IBAN are moved to penalty mode and are actively charged a daily penalty against their balance on every live scan until a verified IBAN is registered.

Watch out for

- Always dry-run first. The live scan writes reminders and creates real withdrawal requests.
- If a forced withdrawal was NOT created for someone over 60 days, they almost certainly lack a verified payout instruction - and their over-age lot is now in penalty mode being charged a daily penalty on each live scan. Register a verified IBAN and re-run promptly; the delay costs the investor money.
- The 60-day clock is per-lot, not per-account; a new deposit does not reset an older lot. The clock runs from each lot's VALUE DATE, so back- or forward-dating a deposit's value date shifts that lot's whole ageing timeline.

6 Record a borrower repayment, run servicing, and handle a late loan

Goal: Book the money a borrower pays back, keep the loan's status accurate, and act when a loan falls behind. · **Who:** Operations admin (servicing).

Before you start:

- Jargon: 'servicing' = ongoing management of a live loan (collecting installments, tracking lateness). 'Installment' = a scheduled repayment. 'late' = at least 5 days past a due date. 'defaulted' = at least 16 days past due. 'status scan' = a job that re-checks each loan's due dates and moves it to late/defaulted as appropriate. 'recovery' = collecting money on a defaulted loan. 'risk note' = a public update to affected investors. Every payment uses the same order: Garanta legal costs/recovery fee, penalty, contractual interest, then principal.

- The loan is 'active' (borrower disbursement completed) or 'late'. A funding-closed loan still marked 'funded' is awaiting disbursement and cannot accept repayments.

- 1

Loans > Manage (loan row)

Open Loans and click 'Manage' on the row of the loan you are servicing, then choose 'Record borrower repayment'.

Servicing and recovery actions live in the Manage dialog. The 'Servicing operations' card below the tables keeps only the status scan and public risk notes. The repayment dialog shows the loan's current repayment schedule so you can see what is due.
- 2

Loans > Manage > Record borrower repayment

For a regular installment, the Amount is FIXED to the outstanding amount of the next due installment and cannot be edited. Enter Booking date, Value date, and Payer name, then submit.

GATES: the loan must be 'active' or 'late' (a 'defaulted' loan must go through Recovery instead), and the borrower must still be able to transact (no explicit compliance hold or Declined/Manual review decision; company KYB is offline). There is no free-amount entry and no 'warning acknowledged' checkbox any more - the old partial/overpayment warning mechanism was removed.
- 3

Loans > Manage > Record borrower repayment

To declare any OTHER amount (lower or higher than the next installment), tick 'Repayment in advance', enter the amount, and select the 'Borrower repayment bank date'.

The universal waterfall first pays any recorded Garanta legal costs/recovery fee and penalty due (both are zero in the current ordinary active/late advance flow). The interest tier pays all unpaid scheduled interest through the bank date plus exact ACT/365 interest: outstanding principal x annual rate bps x elapsed calendar days / (10,000 x 365), up to but excluding the bank date. Future interest is never collected. Only the remainder reduces principal. The future schedule is regenerated as a new version with original future due dates and ACT/365 first-row interest from bank date to due date. Before anything is written, a preview shows the allocation and old/new schedules (POST /api/v1/servicing/admin/borrower-repayments/advance-preview/). A full payoff marks the loan repaid.
- 4

Loans > Servicing operations

Click 'Run status scan' to re-evaluate the loan against today.

The scan only looks at 'funded' and 'late' loans. It flips a loan to 'late' once an installment is 5+ days past due, and to 'defaulted' at 16+ days past due. Run it for the selected loan, or with no loan selected to scan all repayable loans.
- 5

Loans > Servicing operations

For a late or defaulted loan, write a 'Risk note body' and click 'Publish public note' to inform affected investors.

This posts a public servicing update tied to the loan.
- 6

Loans > Manage (loan row)

If the loan is 'defaulted' and you collect money, open Manage and use 'Record a recovery payment' (confirm in the modal).

GATE: recovery is only allowed on a 'defaulted' loan. Record evidenced costs and amounts currently due; the server applies costs/recovery fee, penalty/default interest, contractual interest, then principal. The admin cannot enter a principal-first split. Repayment (steps 2-3) is NOT allowed on a defaulted loan - use recovery.

Result: Repayments are booked against installments at the fixed due amount or as previewed repayments in advance; the loan's status reflects reality (active/late/defaulted); investors are kept informed; recoveries are distributed under the universal waterfall.

Watch out for

- A regular installment can only be declared at the exact outstanding amount of the next due installment - the field is not editable. For anything else, tick 'Repayment in advance' and pick the borrower repayment bank date (defaulted loans go through Recovery instead).
- Always read the repayment-in-advance preview before confirming: it shows the interest/principal allocation and the regenerated schedule side by side with the old one. Nothing is written until you confirm.
- Do not try to record a repayment on a defaulted loan - it is refused. Switch to 'Record a recovery payment' in Manage.
- Run the status scan regularly; lateness/default is driven by it, not by the repayment form.

7 Approve a secondary-market resale listing

Goal: Let an investor resell their loan claim to another investor when the listing needs admin sign-off. · **Who:** Operations admin (marketplace).

Before you start:

- Jargon: 'secondary market' = where existing investors sell their share of a loan ('holding') to other investors. 'listing' = an offer to sell. Most standard, performing listings go live automatically. A listing that needs your decision is in status 'Approval Requested' - this happens when the underlying loan is non-performing (late/defaulted) or otherwise non-standard. 'disclosure note' = a warning shown to potential buyers.
- A listing is sitting in 'Approval Requested'.

- 1

Daily dashboard

Check the 'Secondary approvals' queue on the dashboard for listings pending approval.

This queue holds non-performing or non-standard secondary listings awaiting an admin decision.
- 2

Loans > Secondary-market approvals

Open Loans, go to the 'Secondary-market approvals' card, and pick the listing in the 'Secondary listing' lookup.

The lookup searches by loan title, seller name/email/reference, or listing UUID.

- 3

Loans > Secondary-market approvals

Write a 'Reason' and a 'Buyer disclosure note' explaining the risk (e.g. that the loan is non-performing).
The disclosure note is what buyers will see; be specific about days-past-due and any public servicing note.
- 4

Loans > Secondary-market approvals

Click 'Approve listing' and confirm in the modal.
GATE: approve only works when the listing status is 'Approval Requested'. Approving makes it visible to eligible buyers WITH your disclosure note and an extra acknowledgement step.
- 5

Loans > Secondary-market approvals

Alternatively click 'Reject' (keeps it hidden, records your reason) or 'Remove' (takes an already-visible listing out of buyer view).
GATES: Reject also requires status 'Approval Requested'. Remove works on a listing that is currently 'Active' OR 'Approval Requested'. Each action records the reason in the audit trail.

Result: The listing is either live to buyers with a disclosure, rejected, or removed - and the decision is audited.

Watch out for

- Standard performing listings do not appear here - they go active on their own. Only flagged ones need you.
- Approve and Reject both require the listing to be in 'Approval Requested'; if it has already changed state your action will fail.
- Always fill a meaningful disclosure note - buyers rely on it to understand they are buying a risky claim.

8

Disburse a funded loan to the borrower

Goal: Pay out the raised money to the borrower once a loan has finished funding. · **Who:** Operations admin (finance).

Before you start:

- Jargon: 'funded' = the loan's funding deadline resolved at or above its disclosed minimum subscription and investor money has been committed; the loan now owes a payout to the borrower. 'Disbursement' = the bank transfer that sends the money to the borrower. The scheduled/admin-triggered deadline resolver, not a discretionary close button, turns an expired published campaign into funded. At close the full accepted principal moves into borrower disbursement payable; no fee is accrued at close. 'BANXUM fee' = the borrower success fee, default = funded principal x borrower_success_fee_bps (default 2%); it is withheld from payout and registers as Garanta revenue at disbursement.
- The loan status is 'funded'. If it is still published after its deadline, run Manage > Resolve funding deadline. If it is funding_close_failed, repair the urgent task's cause; scheduled retries apply the same frozen funding result automatically.

- 1

Loans > Manage (loan row)

Click 'Manage' on the funded loan's row and choose 'Borrower disbursement'.
The disbursement action is available in Manage for funded loans. The 'Borrower disbursement' card on Finance ops still exists and records the same operation - use whichever is closer to your workflow.
- 2

Finance ops > Borrower disbursement

If you use the Finance ops card instead, pick the loan in the 'Loan' lookup.
Selecting the loan automatically fills in the Borrower (read-only) and the Currency from that loan. The borrower field becomes read-only and shows the derived borrower ID - you do not pick the borrower separately when a loan is chosen.
- 3

Borrower disbursement form

Review the defaulted Amount and BANXUM fee, set Booking/Value dates, and enter Payee name and Payee account.
By default the form sends the funded principal minus the BANXUM fee (default fee = funded principal x borrower_success_fee_bps, default 2%). The default amount and fee are READONLY: to change them you must overwrite BOTH together and provide a required explanation note. VALIDATIONS: borrower transfer + fee must exactly equal and fully clear the outstanding borrower payable, and the fee must be between 0 and 10% of the funded amount. Integer minor-unit accounting permits no residual tolerance. Use the 'Formatted amount' helper to confirm the figure. The payee is the borrower's bank account that receives the money.
- 4

Borrower disbursement form

Click 'Finalize disbursement'.
GATES (all enforced server-side): the loan must be 'funded'; the loan currency must match; the borrower must match the loan; the borrower must be able to transact (no explicit hold or Declined/Manual review decision; company KYB is offline); transfer + fee must exactly clear the borrower payable; the fee must be between 0 and 10% of funded amount; an override requires the explanation note; and collection cash must cover the transfer. On success the payable is zero, the fee is booked as Garanta revenue, and the loan moves to Active.

Result: The borrower receives the funded principal minus the BANXUM fee (or an explained split that still totals the full payable); the fee registers as Garanta revenue, borrower payable becomes zero, the loan becomes Active, and the action is audited.

Watch out for

- If you see 'Loan must be funded before borrower disbursement', the campaign has not resolved yet - after its deadline use Manage > Resolve funding deadline.
- Do not change the defaulted amount or fee unless you have a documented reason: they can only be overwritten together, and the explanation note is mandatory and audited.
- 'Borrower does not match loan' means the loan/borrower pair is wrong; re-select the loan so the borrower derives correctly.
- Amounts are in minor units - double-check the formatted preview before finalizing a large transfer.

9 Generate a regulatory report and find an action in the audit log

Goal: Produce an accounting/regulatory export and look up who did what, when, in the audit trail. · **Who:** Operations admin (finance / compliance).

Before you start:

- Jargon: 'report type' = the kind of export (e.g. Operational Subledger, Trial Balance, Garanta Accrued Revenue, Bexio Accounting Export, Bank Operations). 'redaction mode' = Redacted (personal data hidden) or Full. 'period preset' = Custom (you set start/end) or a rolling window (Daily/Weekly/Monthly/Quarterly/Yearly/Calendar Year). 'audit log' = an immutable record of every admin action.
- You know which report you need and for which dates.

- 1** Reports (left nav 'Reports') **Open Reports and use the 'Report generation' card.**
It generates accounting, tax, regulatory and operational exports on demand.
- 2** Reports > Report generation **Choose Report type, Output format (Csv / Pdf / Zip), Redaction mode (Redacted / Full), and Period preset.**
If Period preset = Custom, fill both Start date and End / anchor date. For a rolling preset, the End / anchor date is used as the anchor and Start date is ignored.
- 3** Reports > Report generation **Add an optional 'Destination note' and click 'Generate report'.**
On success an artifact panel appears with the filename, a content checksum (SHA-256), the generated timestamp, encoding, a content preview and a manifest.
- 4** Reports > Report generation **Click 'Download artifact' to save the file.**
CSV/text is shown inline; PDF/ZIP comes back base64-encoded and must be downloaded with this button to get the real file.
- 5** Reports > Audit event search **Switch focus to the 'Audit event search' card (right side) and click 'Refresh' to load recent events.**
The table shows, per event: When, Action (e.g. loan.published, ledger.investor_withdrawal_finalized, kyc.manual_review_decision_recorded), Actor (type:id), and Target (type:id). Use it to confirm an operation happened and trace who performed it.

Result: A downloadable, checksummed report file, plus a readable list of recent audited admin actions.

Watch out for

- Pick the right redaction mode - 'Full' includes personal data and should only leave the building when justified.
- For Custom periods you must supply both dates; for rolling presets only the anchor date matters.
- The audit list shows recent reads only; it is for spot-checks and tracing, not a full export.

10 Create a new admin user and restrict an investor account

Goal: Add a colleague to the ops console, and put a hold on a problematic investor account. · **Who:** Superadmin (for creating admins) / compliance admin (for the access change).

Before you start:

- Jargon: 'admin user' = a staff member who can log in to the ops console. 'account access change' = restricting, locking, reactivating, or closing any user (investor or admin) account. Statuses: Active, Restricted, Locked, Closed. 'reason code' = why (e.g. Compliance Hold, Kyc Aml Review, Account Closure). There is no self-serve forgot-password; passwords stay superadmin-managed.
- For creating an admin you need their email, full name, and an initial password.

- 1** Users (left nav 'Users') **Open Users and search the paginated user table by name, email, investor reference, or UUID.**
The table is backend-filtered and shows all account types by default. Regular admins can manage account access. Superadmins additionally see the read-only impersonation action for non-admin users.
- 2** Users > User accounts **Click 'Create admin', fill Email, Full name, and Initial password, then click 'Create admin'.**
Only a superadmin can create admin users. The new admin logs in with email + password + an email code. There is NO forgot-password flow; a superadmin must reset passwords manually.
- 3** Users > User accounts **To act on an existing account, search for it and click 'Access controls' on its row.**
Account access controls have moved out of Compliance and Superadmin Settings so account-level actions are reviewed in one place.
- 4** Users > Account access controls **Set 'New account status' to 'Restricted' (or Locked/Closed), pick a Reason code, and write an Admin note plus Evidence summary.**
'Restricted' limits what the user can do while you investigate; 'Locked' is harder; 'Closed' ends the account.
- 5** Account access controls **If closing an account, tick 'Clean/empty account checked where required for closure', then click 'Apply access change'.**
The clean-account checkbox is an admin attestation that you verified the balance is empty before closure (it is not yet auto-checked by this endpoint). The change is saved and audit-logged.

Result: A new admin can log in; the targeted account is moved to the chosen status with a documented reason in the audit trail.

Watch out for

- No forgot-password exists - record the initial admin password securely and hand it over safely.
- Closing an account asserts it is empty; do not tick the clean-account box unless you actually confirmed there is no balance or holding.
- Always provide a reason code and note; access changes are compliance-sensitive and audited.
- Users cannot be deleted from the directory - only their access status is changed.

11 Work the daily dashboard from open to empty

Goal: Start your shift, read every queue, triage by priority, and jump to the right module to clear each item. · **Who:** Operations admin (any).

Before you start:

- Jargon: 'queue' = a short list of pending work in one area. 'SLA' = service-level deadline; an item past its due date is 'Overdue'. 'priority' = Urgent/High/Normal/Low. The dashboard is read-and-route: you read context here, then go to the module that owns the action.
- You are signed in. The dashboard is the default landing screen ('Daily dashboard' in the nav).

- 1

Daily dashboard (KPI tiles)

Read the four tiles at the top: Open queue items, High priority (with urgent count), Overdue SLA, and Finance actions.

'Finance actions' sums bank exceptions, withdrawals, forced withdrawals, FX settlement, and reconciliation breaks - your money-movement load for the day.
- 2

Daily dashboard (Queues list)

Scan the left-hand queue tabs and their counts: Admin tasks, KYC reviews, Bank exceptions, Withdrawals, Forced withdrawals, Balance ageing, Funding loans, Servicing due, Loan risk, Secondary approvals, FX settlement, Failed emails, Reconciliation breaks.

Each tab shows a short label, its group (General/Compliance/Finance/Marketplace/Servicing/Comms), and an open count. Click a tab to load its items on the right.
- 3

Daily dashboard (Queue panel)

Open each non-empty queue; work Urgent and Overdue (highlighted) rows first.

Each row shows Item title, Status, Priority, Due, Amount, and the underlying Object (type + id). Overdue rows are visually flagged. Click a row to open a drawer with full metadata and context.
- 4

Daily dashboard > queue drawer

Act on withdrawals in their drawer; route other records to their owning module.

NORMAL/FORCED WITHDRAWALS: after the bank transfer executes, enter booking/value date, collection account and note, then Finalize; or Cancel before execution to release the reserved balance. ROUTING FOR OTHER ITEMS: KYC -> Compliance; bank exceptions/balance ageing/FX -> Finance ops; funding/risk/servicing -> Loans; secondary approvals -> Loans; admin tasks -> Tasks.
- 5

Daily dashboard (Reconciliation breaks queue)

When the 'Reconciliation breaks' tab is selected, click 'Create tasks' to turn current breaks into trackable admin tasks, then refresh.

'Create tasks' syncs reconciliation-break snapshots into the task list (it reports how many were created vs already existed) so nothing falls through the cracks.
- 6

Daily dashboard

After acting in each module, return to the dashboard and click 'Refresh'; repeat until counts reach zero.

Also scan the 'Currency operations' table at the bottom (per-currency Available, Investable, Withdraw-only, Overdue, Frozen, Penalty, Pending withdrawals, Pending bank ops, FX unsettled) to confirm money positions look sane before you finish.

Result: Every queue is empty or down to non-actionable items; urgent and overdue work is cleared first; reconciliation breaks are converted into tracked tasks.

Watch out for

- Only withdrawal and forced-withdrawal drawers currently perform the owning action. Other queue drawers still route you to the relevant module.
- Do not ignore Overdue (SLA) rows - they are past their deadline and should be cleared before fresh work.
- Refresh after acting; counts do not update live while you are away in a module.

12 Run a staging fast-forward QA test and revert it

Goal: Safely test time-based behavior such as funding-window/day-60 balance ageing, forced withdrawals, penalty mode, late/default transitions, campaign expiry, and scheduled notices without waiting real days. · **Who:** Active regular admin or superadmin on staging/local only.

Before you start:

- You are on the staging deployment (staging.nxnarena.com), not production. QA mode is blocked in production.
- You have a clear test plan: which investor, loan, balance lot, or campaign you are going to observe, and what date outcome you expect.
- You understand that revert restores database state only. External emails/SMS/provider calls already sent, downloaded files, object-storage artifacts, and anything outside the database are not rolled back.

- 1

QA mode

Open the QA mode section and read the environment, clock and restore points.

Regular active admins have access when staging/local allows QA. Production never exposes this section. Coordinate with all testers before changing the shared database.

- 2

QA mode

Use the enabled regression seed, or enter QA mode if the environment owner has not enabled it yet.

The regression seed already contains the starting clock, accounts, balances and loans. Create snapshot optionally saves a later checkpoint without replacing the seed. Without a manual snapshot, Restore seed is the default.
- 3

Relevant module before fast-forward

Create or select the records you want to test.

Examples: declare a deposit with a known value date, publish a campaign with a short deadline, create a funded loan with due installments, or register a payout instruction before testing forced withdrawals.
- 4

QA mode

Enter the number of days to advance and run the fast-forward.

The system advances simulated business time day by day. For every crossed Europe/Zurich business date it runs the daily scheduled jobs: balance ageing and penalty charging, servicing status scan, primary funding-expiry scan, reconciliation-break task sync, Loan Originator settlement-task sync, Loan Originator opportunity/activation lifecycle scan, and due email dispatch.
- 5

Daily dashboard / Finance ops / Loans

Inspect the effects exactly as you would in normal operations.

Check that ageing buckets changed, forced withdrawals appeared, penalty-mode lots charged, loans moved to late/defaulted, campaigns expired, reconciliation tasks synced, and expected notifications were queued or sent.
- 6

QA mode

Save evidence outside the database. Enter REVERT QA DB and choose Restore seed for a clean regression branch, or Restore snapshot for the saved checkpoint. Confirm the selected target.

The selected database state and clock are restored atomically. The restoring admin normally keeps access through a fresh session; everyone else signs in again. If the admin's restored credentials or permissions differ, that admin signs in again too. Verify the restored balances and catalogue before continuing.

Result: Daily jobs run for the advanced dates. Restore seed returns to the same original seed and QA clock on every run; Restore snapshot returns to the separately saved checkpoint.

Watch out for

- Do not use QA mode with real customer funds or any test where sent emails/SMS/provider calls would create confusion. Database revert does not unsend messages.
- Do not run normal scheduled jobs concurrently with a manual fast-forward test unless instructed by the runbook; fast-forward already runs the relevant daily jobs.
- Restore seed between independent branches. Its simulated clock intentionally remains enabled at the seed date; use the matching dated CSV pack. Do not replace the original seed with a later checkpoint.

13 Import, fund, service and settle a Loan Originator claim

Goal: Fund an at-par LO subscription, activate it automatically at close, record repayments and settle the LO externally. · **Who:** Loans admin plus Finance Operations admin.

Before you start:

- The Loan Originator has completed off-platform KYB/AML, is Active, and has verified settlement account details.
- Review the contract, servicing export and bank evidence offline. Prepare anonymized disclosure and a UTF-8 CSV matching imports_examples/README.md.
- The loan is performing, unheld, not repaid, and has more than 30 calendar days to maturity.

- 1

Loans > Loan Originators

Select or create the originator; verify its identity, jurisdiction, settlement details and Active status.
Active confirms completed offline review. KYB references are optional. The LO has no platform login or wallet.
- 2

Loans > Create originator claim

Enter borrower disclosure, funding deadline, boundary installment/date/principal, coupon, participation rates, minimum investment and retention.
One currency unit buys one unit of post-boundary principal. Coupon is the borrower's rate; interest/penalty participation defines investor rights. The boundary installment belongs wholly to the LO.
- 3

Originator claim import

Upload the full schedule and all payments through the import as-of date.
Check outstanding principal, maturity and validation results. Every component must reconcile; investigate errors rather than altering evidence to pass validation.
- 4

Loans > Manage

Choose Publish funding round; review all terms and the schedule, then confirm.
Check public disclosure, participation, boundary principal and the maximum 50-day inclusive subscription window. Inactive originators, holds/adverse states, impaired loans and invalid imports block publishing.
- 5

Investment Opportunities

In QA, place an at-par subscription and inspect the result.
A partial subscription reserves eligible balance in funding escrow. Filling the round closes and activates it automatically. Repeating the same idempotency key must not duplicate the order.
- 6

Loans > Manage > Close funding round

For deadline closure, use the resolver or Close funding round after the deadline.
Any positive round closes; an empty round cancels. Close creates holdings, fixed entitlements and LO payable atomically. A failed close preserves reservations, raises an urgent task/email, and retries automatically after the cause is repaired.
- 7

Loans > Manage

After the boundary payment reaches Garanta, choose Record borrower repayment / schedule revision.
Enter the actual bank evidence and reconciled replacement CSV. Holdings already exist. The entire boundary payment is payable to the LO, with zero credited to investors.
- 8

Loans > Manage

Record later repayments with complete replacement CSV history. Review investor credits, LO payable and Garanta costs in the confirmation and retained history.
Priority is legal/recovery costs, penalty, interest, principal. Principal follows ownership; interest and penalty use the declared participation rates.
- 9

Finance operations > Originator settlement

Reconcile the originator/currency batch and record the external transfer with bank evidence.
Settle the complete batch once. Tasks start at day 3; escalate before day 5. Partial settlement is not supported.
- 10

Reconciliation / Tasks

Create a reconciliation snapshot, check for breaks and resolve the settlement task.
Funding escrow is tracked before close; LO payable remains tracked until external settlement.

Result: Active holdings start at funding close; repayments and external LO settlements remain reconciled and auditable.

Watch out for

- Use LO actions, not direct-loan disbursement or servicing forms. Never invent a boundary receipt to activate holdings.
- Borrower legal name is private unless explicitly published per loan; bank details and settlement state remain internal.
- Holds and legacy repair exceptions preserve reservations. Investigate promptly. A subscribed expired or failed round requires repair and automatic retry, not discretionary cancellation; historical upgrade exceptions retain their reviewed legacy resolution path.
- Only performing originator holdings may be resold; late/defaulted transfers remain blocked.

Glossary & quick reference

Key terms

P2P lending (peer-to-peer lending)	The core business. Many individual investors put up the money to fund a loan to a business borrower. The borrower repays the loan with interest over time. Investors earn that interest. BANXUM is the marketplace that connects the two sides and handles the money and paperwork.
BANXUM	The brand name of the marketplace platform. It is operated by Garanta Finanzgruppe AG, a Swiss financial group. You work inside its internal admin console at /admin.
Garanta Finanzgruppe AG	The Swiss company that runs BANXUM. In the system, money and fee accounts owned by the operator are labelled "Garanta" (for example Garanta accrued revenue, Garanta in, Garanta out).
Lender / Investor	A person or company that deposits money and uses it to fund loans, then earns interest. "Lender" and "investor" mean the same thing here. An account can be a natural-person lender (an individual) or a legal-entity lender represented by a person.
Borrower	A vetted business that receives loan money and repays it with interest. Borrowers are companies (called borrower entities), not individuals. Examples of entity types: Swiss company, non-Swiss company, real estate project company, special purpose vehicle.
KYC (Know Your Customer)	The identity and background checks done on a person before they are allowed to use money on the platform. It confirms who they are and screens them against risk lists. Used for lenders/investors. A lender who has not passed KYC cannot transact.
KYB (Know Your Business)	Company identity, ownership and AML checks, completed and retained offline by Garanta. Platform company files are optional. Explicit borrower holds and Declined/Manual review decisions block transactions; missing or expired optional records do not.
AML (Anti-Money-Laundering)	The set of legal checks that stop the platform being used to launder illegal money. KYC and KYB screening feed into AML. Reviews are often labelled "KYC/AML".
Didit	The outside vendor (third-party provider) that runs the automated identity-verification and screening checks. Most KYC cases use Didit. When Didit cannot give a clear answer, the case is routed to Garanta staff for manual review.
Manual review	A KYC/KYB case the automated provider could not decide on its own, so a human admin must make the call. Reasons include PEP review, high-risk review, adverse-media review, sanctions review, provider decline, inconclusive provider result, or a document/identity issue. The admin can approve, decline, request re-verification, or reopen the review.
Sanctions hit	Screening found the person or business on an official sanctions list (people/entities that the law forbids doing business with). This blocks the account until reviewed.
PEP (Politically Exposed Person)	Someone in a senior public role, or close to one (for example a government minister or their family). They are not banned, but they need extra scrutiny because of higher corruption risk. A PEP hit triggers manual review.
Adverse media	Negative news found about the person or business (for example reports of fraud or crime). An adverse-media hit triggers manual review before the account can proceed.
Compliance hold	A manual flag on a borrower that blocks it from transacting, even if its KYB is otherwise approved. Used when compliance staff need to pause activity.
Primary market	Where brand-new loans are funded for the first time. A loan is published, investors commit money to it, and once it is fully funded the money goes to the borrower. This is the original sale of the loan.
Secondary market	Where an investor who already holds a piece of a loan can sell that holding to another investor before the loan finishes. The original loan does not change; only who owns the right to its future repayments changes.
Holding	An investor's stake in a specific loan: the share of the principal they funded and are owed repayments on. A holding is the thing that gets sold on the secondary market.
Maker / Taker	On the secondary market, the maker is the seller who lists a holding for sale; the taker is the buyer who purchases it. Each pays a separate fee (maker fee, taker fee).
Transfer price	The amount the buyer pays the seller for a secondary-market holding. It can be at a discount or premium to the outstanding principal (shown in basis points), plus any accrued interest.
Accrued interest	Interest that has built up on a loan but has not yet been paid out. On a secondary sale, the buyer compensates the seller for interest earned up to the sale date.
Balance lot	A single tracked batch of an investor's money, recorded separately by where it came from (a deposit, a repayment installment, a recovery distribution, secondary-market proceeds, FX proceeds, a refund, or a correction). The platform tracks each lot's own age and how much is still available, invested, converted, withdrawn, or penalized. Money is used oldest-lot-first.
Minor units	Money is stored as whole numbers of the smallest currency unit (cents/centimes) to avoid rounding errors. A field ending in "_minor" holds minor units. Example: 150000 minor units = CHF 1,500.00. The console formats these into normal amounts for display.

Basis points (bps)	A unit for rates and fees. 100 bps = 1%. So an interest rate of 850 bps means 8.50%. Used for interest rates, fees, discounts/premiums, and loan-to-value.
LTV (loan-to-value)	How big the loan is compared with the value of the collateral backing it, shown in basis points. Lower is safer. A warning is raised if collateral value is zero or smaller than the loan.
Collateral	Assets a borrower pledges to back a loan, so investors can be repaid if the borrower fails. Types include real estate, corporate or personal guarantees, receivables, invoices, equipment, inventory, securities or share pledges, and cash.
Risk rating	A credit grade for a loan, from AAA (safest) down through B and C grades to D, or "unrated". It signals how risky the loan is to investors.
Principal	The original loan amount borrowed, before interest. "Committed principal" is how much investors have pledged so far toward funding it.
Financeable principal	The amount investors fund on a loan (the loan's principal_minor). Every loan's repayment schedule is generated from the financeable principal. If funding closes partially, the financeable principal drops to the actually funded amount and the schedule is regenerated with the same term, interest rate, and percentage BANXUM fee.
Refinancing loan	A loan where BANXUM lenders refinance part or all of the outstanding principal of an existing loan (ongoing or new). The admin ticks 'Refinancing loan' at creation and declares the original loan data: original contractual principal, original interest rate, original term, and original loan start date. Functionally it behaves exactly like a standard loan - its own schedule comes from the financeable principal. Investors see a 'Refinanced loan' badge and the informational original schedule on the loan detail page.
Original loan schedule	For a refinancing loan, the purely informational repayment schedule computed from the admin-declared original loan data. It is never persisted and never serviced. During publish, the admin ticks which original installments were already paid before publication (a contiguous prefix of past-due rows); the ticks are investor information only and never affect servicing.
Repayment in advance	The way to declare any borrower repayment other than the fixed next-due installment (defaulted loans go through recovery instead). The admin ticks 'Repayment in advance' and selects the borrower repayment bank date. The amount pays all unpaid scheduled interest due on or before the bank date, plus pro-rata accrued interest up to that date; the remainder reduces principal, and the future schedule is regenerated as a new version. A preview of the allocation and both schedules must be confirmed before anything is written. A full payoff marks the loan repaid.
BANXUM fee (borrower success fee)	The percentage fee withheld from the borrower disbursement, default 2% of the funded principal (borrower_success_fee_bps). No fee is accrued at funding close (the planned fee is recorded as evidence only); the fee registers as Garanta/BANXUM revenue at disbursement. The default disbursement amount and fee are readonly and can only be overwritten together with a required explanation note; the fee must stay between 0 and 10% of the funded amount.
Investor reference	A short unique code (up to 10 characters) automatically assigned to each lender account. It identifies the investor across the system and is unique per lender.
Payment reference	A code written on a bank transfer so the platform can match incoming or outgoing money to the right deposit, withdrawal, or settlement. Stored on bank operations and withdrawal records.
Collection account	The platform's own bank account where investor money and repayments are collected and held. Bank operations record which collection account a transfer touched.
Bank operation	A recorded movement of real money in or out of the platform's bank, such as a lender deposit, lender withdrawal, borrower disbursement, borrower repayment, or an FX settlement. Each must be matched (reconciled) to the internal ledger.
Ledger	The platform's internal double-entry bookkeeping system. Every money event creates a journal entry with balanced debit and credit postings across accounts (for example collection cash, investor balance liability, escrow, fee revenue).
Payout instruction (IBAN)	An investor's saved bank-account details (IBAN and account name) used to send withdrawals. A checksum-valid source IBAN is verified automatically when an admin declares the matching deposit. Additional distinct IBANs are additive and remain unusable until an admin verifies them; verifying one does not disable existing verified accounts.
IBAN	International Bank Account Number: the standard format for identifying a bank account when sending money. It is the destination for an investor's payout.
Withdrawal	An investor's request to take their available money out of the platform and have it sent to their bank account. Garanta executes the bank transfer, then marks the request finalized.
Forced withdrawal	A withdrawal the platform starts on its own (not requested by the investor) to return money that has sat uninvested too long. Triggered by balance ageing at the day-60 window for regulatory reasons. Marked with the "is_forced" flag.
Ageing	Tracking how long each balance lot of uninvested money has been sitting. The platform enforces its 60-day holding limit: approaching-deadline lots surface for action, and day-60 lots enter the return process. Investment eligibility depends on the loan's remaining funding window.
Disbursement	Paying out the loan money to the borrower once funding has closed. At close the full accepted principal moves into the borrower disbursement payable; at disbursement the admin by default sends the funded principal minus the BANXUM fee, and the fee books as Garanta revenue. Available from the Loans table (Manage > Borrower disbursement, for funded loans) and from the Finance ops card.
Escrow	A holding account where committed funding money sits temporarily between the moment investors commit it and the moment it is disbursed to the borrower.

Servicing	The ongoing management of a live loan: tracking the repayment schedule, collecting each installment from the borrower on its due date, and distributing repayments to investors. Servicing and recovery actions are recorded from the Loans table Manage dialog; a regular installment is declared at the fixed outstanding amount of the next due installment, and any other amount uses 'Repayment in advance'.
Installment	One scheduled repayment in a loan's repayment plan, with its own due date and split between principal and interest. The full set of installments is the repayment schedule.
Recovery	Efforts to get money back from a borrower that has stopped paying (is late or in default), for example by enforcing collateral. Every recovered payment follows the same fixed order: Garanta legal costs/recovery fee, penalty/default interest, contractual interest, then principal. The order cannot be changed per loan or by the operator.
Default	A loan where the borrower has failed to repay as agreed for long enough to be declared in default. It moves into recovery work and may eventually be written off.
Write-off	Formally recording that a loan's outstanding amount is treated as a loss because it is judged unrecoverable.
Reconciliation	Checking that the platform's internal ledger matches the real bank balances and that investor balances add up. Done by comparing a reconciliation snapshot (bank balance vs. ledger figures) on a given date.
Reconciliation break	A mismatch found during reconciliation: the ledger and bank disagree, a balance has the wrong sign, or an investor's balance fails an integrity check. Breaks must be investigated and resolved.
Suspense / unmatched cash	Money that has arrived in or left the bank but cannot yet be linked to a specific deposit, repayment, or instruction. It is parked in a suspense account until an admin matches it.
Outbox email	Transactional system emails (login codes, confirmations, notices) are queued in an outbox before being sent, so delivery can be tracked and retried.
Dead-letter email	An email that failed to send after the system gave up retrying. It lands in a dead-letter state and shows in the Failed emails queue for an admin to review.
FX (foreign exchange / currency exchange)	Converting an investor's balance from one currency to another inside the platform. The investor gets a quote (rate plus fee), and on acceptance an exchange is executed, producing balance in the new currency.
FX quote	A priced, time-limited offer to convert one currency to another at a given rate, with the platform fee shown. It expires if not used and passes a sanity check against the previous day's average rate.
FX settlement (external settlement)	Internal currency conversions are netted and then actually settled with a real bank in the outside market. An admin declares the external settlement: the real amounts sold and bought, the actual rate, and the linked bank operations. Until declared, internal FX shows up in the FX settlement queue.
Audit event	An append-only (never edited or deleted) record of who did what and when. The system logs these for account-status changes, loan changes, KYC/KYB decisions, secondary-market listing changes, and FX actions, capturing the actor, before/after status, reason, and notes.
Append-only	A record type that can be added to but never changed or removed, so the history stays trustworthy. Most event and ledger records are append-only.
Idempotency key	A unique tag attached to a money operation so that, if the same request is sent twice, it is only processed once. Prevents accidental double deposits, withdrawals, or postings.
Sensitive action	A higher-risk operation that requires an extra one-time confirmation code, such as admin login, a withdrawal, a bank-account change, an FX exchange, a primary investment, or a secondary-market listing or purchase.
Reverification	Asking a customer to redo their identity/business verification, for example because the previous one expired or new information is needed. The case status becomes "re-verification required".
Loan Originator (LO)	A professional lender that already owns loans to final business borrowers and offers part of a performing loan through BANXUM. The originator is an admin-managed accounting/settlement entity with off-platform KYB; it has no BANXUM login.
Originator claim	Participation in an existing loan offered by a Loan Originator through a finite funding round. Cash reserves at par during funding. Funding close creates an active holding automatically; the boundary installment remains wholly payable to the LO and investor component rights start after it.
Coupon versus participating yield	Coupon is the contractual annual rate paid by the final borrower. A current originator subscription separately declares the investor's interest and penalty participation. The displayed Yield is a nominal coupon-participation indicator, not a guaranteed effective return; one unit of cash buys one unit of principal at activation.
Dated entitlement	The immutable post-boundary principal and component rights recorded when the investment activates at funding close. No investor interest accrues during funding; the boundary installment belongs entirely to the LO.
Originator payable	An accounting liability owed by Garanta to a Loan Originator. Activated subscription principal and the originator share of later borrower repayments accumulate here until Finance Operations executes and records a complete external settlement batch.
Statuses you will see	
Account: Pending KYC	A new account that has not yet passed identity checks. It can log in to resume onboarding, but it cannot use financial features yet. This is the default state for a new user.
Account: Active	The account is in normal standing. Money features also require a verified phone and, for natural-person lenders, approved KYC. Company KYB is handled offline.

Account: Restricted	The account is limited and cannot log in. Used while under review or held.
Account: Locked	The account is blocked from logging in, typically for security or compliance reasons.
Account: Closed	The account is permanently shut and cannot log in.
Account type: Natural-person lender	An individual investor account.
Account type: Legal-entity lender representative	A person who acts for a company that invests on the platform.
Account type: Admin / Superadmin	Internal Garanta staff. Superadmin has the highest level of access.
KYC: Not started	Identity verification has not begun. Blocks transacting.
KYC: Pending	Verification is in progress at the provider; no decision yet. Blocks transacting.
KYC: Approved	Identity checks passed. The lender can transact.
KYC: Declined	Verification was rejected. The lender cannot transact.
KYC: Manual review	The automated check was inconclusive; a Garanta admin must decide. Blocks transacting. Appears in the KYC reviews queue.
KYC: High risk	Screening flagged the person as higher risk; needs review before they can proceed.
KYC: Sanctions hit	Matched a sanctions list. Blocked pending review.
KYC: PEP hit	Flagged as a politically exposed person. Needs extra scrutiny before proceeding.
KYC: Adverse media hit	Negative news was found about the person. Needs review before proceeding.
KYC: Expired	A previously valid verification has aged out and is no longer accepted. Blocks transacting until redone.
KYC: Re-verification required	The customer must redo verification before continuing. Blocks transacting.
KYB (borrower): Not started	Optional platform record has not been started. Garanta must already have completed company checks offline; this value alone does not block transactions.
KYB (borrower): Pending	Optional platform record is pending. This alone is not a transaction block; company review is handled offline.
KYB (borrower): Approved	Optional record of completed company checks. Explicit compliance holds still block transactions.
KYB (borrower): Declined	Business verification was rejected. The borrower cannot transact.
KYB (borrower): Manual review	An explicit unresolved company review decision. Blocks borrower transactions until reviewed and resolved by Garanta.
KYB (borrower): Expired	Optional platform record has expired. This alone does not block transactions; Garanta manages company review offline.
KYB (borrower): Re-verification required	Optional company review reminder. Garanta handles it offline; this value alone is not a transaction block. Use an explicit hold for a restriction.
Loan: Draft	Being prepared by an admin; not visible to investors and not open for funding.
Loan: Published	Live on the primary market and open for investors to commit funding (until the funding deadline).
Loan: Funded	Direct-loan funding has closed and principal is payable to the borrower pending disbursement. Current LO v2 investments become Active automatically when funding closes, without waiting for a borrower payment.
Legacy subscription: upgrade exception	Historical closed reservations are upgraded automatically from their original schedule. New subscriptions never enter this stage. A held or inconsistent historical record retains funds and raises a repair task/email; resolve the cause and rerun the lifecycle scan, or cancel/refund.
Loan: Funding close failed	The deterministic close could not finish. The opportunity is hidden and investor funds remain reserved. Repair the cause identified by the urgent task and operations alert. Automatic retries keep the published outcome; admins cannot cancel a qualified failed round instead.
Loan: Late	The borrower has missed a payment and is past due, but not yet declared in default.
Loan: Defaulted	The borrower has failed to repay as agreed; the loan moves into recovery work.
Loan: Repaid	The borrower paid everything back. The loan is finished successfully.
Loan: Written off	Recorded as a loss because the outstanding amount is judged unrecoverable.
Loan: Cancelled	The loan was withdrawn before it became active (for example funding was cancelled).
Bank operation: Reconciled	The bank movement has been matched to the internal ledger. This is the normal, settled state.
Bank operation: Pending review	The bank movement needs an admin to check it before it can be allocated. Appears in the Bank exceptions queue.
Bank operation: Unmatched	Money arrived or left but is not yet linked to anything. Sits in suspense; appears in the Bank exceptions queue.
Bank operation: Returned	The transfer was sent back (for example a failed or bounced payment).
Balance lot: Available	Money remains in the lot, but what it can be used for depends on the ageing bucket. Before day 60 it may fund loans whose remaining subscription window fits within its remaining holding time; eligible FX preserves that deadline; at/after day 60 it must be returned or moved to penalty handling.
Balance lot: Consumed	The lot is fully used up (invested, converted, or withdrawn); nothing left available.
Balance lot: Frozen	The lot is temporarily held and cannot be used, for example during a review or hold.
Balance lot: Penalty mode	The lot passed the 60-day limit without a verified payout IBAN. It is charged a daily penalty, cannot be invested, and currently blocks FX exchanges and secondary-market purchases until the overdue balance is resolved.

Balance lot: Penalty exhausted	The lot's penalty handling has run its course and nothing remains available.
Withdrawal: Requested	The withdrawal has been asked for and is waiting for Garanta to execute the bank transfer.
Withdrawal: Finalized	The bank transfer was executed and the withdrawal is complete.
Withdrawal: Cancelled	The withdrawal was called off and the money returned to the investor's balance.
Payout instruction: Active	The investor's current bank details on file for receiving payouts in a currency. Only one can be active per currency.
Payout instruction: Disabled	An old or turned-off set of bank details, no longer used for payouts.
Secondary listing: Active	The holding is live for sale on the secondary market and can be bought.
Secondary listing: Approval requested	A non-standard or non-performing listing is waiting for an admin to approve before it goes live. Appears in the Secondary approvals queue.
Secondary listing: Rejected	An admin refused to approve the listing; it does not go live.
Secondary listing: Removed	An admin took the listing down.
Secondary listing: Sold	A buyer purchased the holding; the listing is complete.
Secondary listing: Cancelled	The seller withdrew their own listing before it sold.
Secondary listing publication: Automatic	The listing went live on its own because it met the standard rules; no admin approval was needed.
Secondary listing publication: Admin approved	The listing required and received an admin's approval before going live.
FX exchange: Completed	The internal currency conversion was executed successfully.
FX external settlement: Declared	An admin has recorded the real-world bank settlement for netted FX activity, including actual amounts, rate, and linked bank operations.

Dashboard queues

Admin tasks (Tasks)	Open internal to-do items, deadline (SLA) follow-ups, and operational notes that staff need to act on. General catch-all work list.
KYC reviews (KYC)	Identity-check cases that the Didit provider sent for a human decision. A Garanta admin must approve, decline, or ask for re-verification.
Bank exceptions (Bank)	Bank or payment-provider movements that are unmatched or pending review. They block money from being allocated in the ledger until an admin resolves them.
Withdrawals (Withdrawals)	Investor withdrawal requests waiting for Garanta to send the bank transfer and then mark them finalized.
Forced withdrawals (Forced)	Day-60 return-of-funds withdrawals the system created automatically because money sat uninvested too long. These return idle cash to the investor.
Balance ageing (Ageing)	Balance lots that are near or past the 60-day holding limit for holding idle investor cash. They need action so the platform stays within the rules.
Funding loans (Funding)	Published loans on the primary market that are near their funding deadline or need a close review of their funding progress.
Servicing due (Servicing)	Loan installments and borrower repayment actions that fall inside the current due window and need handling.
Loan risk (Risk)	Loans that are late, defaulted, or in recovery and need notes, a status review, or recovery work.
Secondary approvals (Secondary)	Secondary-market listings that are non-performing or non-standard and are waiting for an admin to approve or reject them.
FX settlement (FX)	Internal currency-exchange activity that still needs an admin to declare its real-world external bank settlement.
Failed emails (Emails)	Transactional emails that failed to send and landed in the dead-letter state. They need an admin to review and decide what to do.
Reconciliation breaks (Recon)	Mismatches found when comparing the ledger to the bank: ledger-vs-bank differences, wrong-sign anomalies, or investor-balance integrity failures. They must be investigated and cleared.
